# Energy Levels of Chromium, Cr I through Cr XXIV

Jack Sugar and Charles Corliss

Institute for Basic Standards, National Bureau of Standards, Washington, D.C. 20234

The energy levels of the chromium atom in all of its stages of ionization, as derived from the analyses of atomic spectra, have been compiled. In cases where only line classifications are given in the literature, level values have been derived. The percentages for the two leading components of the calculated eigenvectors of the levels are given where available. Ionization energies and g-factors are also given.

Key Words: Atomic energy levels; atomic spectra; chromium.

## 1. Introduction

This is the second of a new series of compilations of atomic energy levels in the iron period (the 3d shell) that supplies a much needed updating of the compilation of C. E. Moore (1952). The first by Reader and Sugar (1975) gave energy level data for all stages of ionization of iron. Since the introduction in that article explains details of the compilation that apply equally to the present work, it is reproduced here with appropriate changes.

We give the energy levels of the chromium atom and all of its ions as derived from the analyses of atomic spectra. These include primarily levels arising from outer-shell excitations. For the high stages of ionization, inner-shell excitations are included since the distinction in energy becomes less clear.

For most of the level systems given here the energy level data have been drawn from widely scattered sources in the literature. For many of the ions the original papers do not give energy level values, but only classifications of observed lines. In these cases we have derived the level values for inclusion here. We have also derived some of the ionization energies from the observed levels.<sup>1</sup>

For a large number of ions, too few levels are known to permit the derivation of an experimental value of the ionization energy. In these cases we have quoted estimated values obtained by extrapolation along isoelectronic sequences. Although it is not possible to give a quantitative uncertainty for these extrapolated values, they are probably accurate to a few units of the last significant figure listed. Edlén (1971) has recently published a set of semiempirical formulas that could be used to obtain new estimates for a number of the ionization energies.

Although in most cases we used only published papers as sources of data, unpublished material was included when it constituted a considerable improvement.

Nearly all of the data are the results of observations of various types of laboratory light sources. However, they are sometimes supplemented by data obtained from solar observations. This is particularly true where spin-forbidden lines are required to establish the absolute energy of a system of excited levels and also where parity-forbidden transitions between levels of a ground configuration are used to obtain accurate relative energies for the low levels. Whenever both solar data and equivalent laboratory data were available for a given level system or part of a level system, preference was generally given to the laboratory data in order to avoid the problem of blended lines of various elements in the solar spectra. Our source of data was always the original literature. For a convenient source of wavelengths of chromium lines below

<sup>1</sup> Values for ionization energies are usually derived in their equivalence in cm<sup>-1</sup>. The conversion factor 8065.479 cm<sup>-1</sup>/eV, as given by E. R. Cohen and B. N. Taylor, J. Phys. Chem. Ref. Data 2, 663 (1973), was used to obtain values in eV.

2000 Å we refer the reader to the recent compilation by Kelly and Palumbo (1973).

Almost every level in the present compilation is accompanied by a quantum mechanical designation (or name). The treatment of the level designations is sometimes a troublesome question. For a given configuration a certain number of terms of various types ( $^5\text{H}$ ,  $^7\text{H}$ , etc. in  $LS$  coupling, for example) are theoretically expected, and spectroscopists have traditionally tried to give such definite names to terms, even though  $g$  values, intensities, and arrangement of the levels may indicate that no such "pure" name is appropriate. It is thus of interest to know just how well the name of a level describes its quantum properties. To this end, we have included the results of theoretical calculations which express the percentage composition of levels in terms of the basis states of a single configuration, or more than one configuration where configuration interaction is important.

The percentage compositions have the following meaning. Suppose that for a given configuration there is a set of  $n$  basis states, written symbolically as  $\psi_1, \psi_2, \dots, \psi_n$ . Usually these basis states are taken to be the  $LS$  states for a configuration, but other coupling schemes are often used. Then the eigenvector  $\psi_A$  of an actual energy level  $A$  can be expressed as

$$\psi_A = \alpha_1 \psi_1 + \alpha_2 \psi_2 + \dots + \alpha_n \psi_n,$$

where  $\alpha_1^2 + \alpha_2^2 + \dots + \alpha_n^2 = 1$ . The squared quantities  $\alpha_1^2, \alpha_2^2$ , etc. represent the percentage composition of a given level. Generally, levels are given names corresponding to the basis state having the largest percentage. The percentage compositions are determined in the theoretical calculations by finding the eigenvalues and eigenvectors of the energy matrix.

In the columns of the present tables headed "Leading components" we give first the percentage of the basis state corresponding to the level's name; next the second largest percentage together with the related basis state. We have not listed any second component whose percentage is less than 5 percent. The percentages show that in many cases it is not possible to group the levels into meaningful terms. However, where levels have been arranged into terms in the original papers or in subsequent theoretical calculations, we have generally retained these groupings.

Of course, the percentage compositions cannot be considered to be as reliable as experimental quantities inasmuch as a new calculation using a different approximation, such as the introduction of configuration interaction where none had been used before, might yield a different set of percentages. For some levels the percentages may change drastically in a new calculation. Therefore the compositions given here should be considered only as a useful guide to the true quantum character of the levels.

It should be noted that the theoretical calculations involved in obtaining the percentage compositions are of two types. The semiempirical method treats the radial integrals appearing in the energy matrix as parameters whose values are determined by a least-squares fit to the observed levels. In the ab initio method, the radial integrations are carried out with wavefunctions found by solving the wave equation for a given atom, as in a Hartree-Fock calculation or variation thereof. In the

present tables, the percentages are mostly taken from published least-squares level-fitting calculations. When only ab initio calculations are found in the literature, we have used them if there appears to be a reasonable correspondence with the experimental data. For higher ionization stages there has been less effort to relate quantitatively the theoretical results to the observations by means of least-squares calculations.

For configurations of equivalent electrons, repeating terms sometimes occur. These are generally distinguished by their seniority number. In the present compilation they are designated in the notation of Nielson and Koster (1963). For example, in the  $3d^5$  configuration there are three  $^2\text{D}$  terms with seniorities of 1, 3, and 5, respectively. These terms are denoted as  $^2\text{D}1$ ,  $^2\text{D}2$ , and  $^2\text{D}3$  by Nielson and Koster.

The labeling of terms by lower case letters,  $a, b, c$ , etc. (for example  $a^5\text{D}$ ,  $z^5\text{D}^o$ , etc.) has been dropped, except for CrI and II where their use in connection with various wavelength tables makes their retention desirable.

We used the following procedure for carrying out the present compilation. First, a complete list of references for each stage of ionization was drawn up, based primarily on the following bibliographies:

- i. papers cited by Moore (1952)
- ii. C. E. Moore (1969)
- iii. L. Hagan and W. C. Martin (1972)
- iv. card file of publications since June 1971 maintained by the NBS Atomic Energy Levels Data Center

Then, each paper was scanned for new energy level data and the levels compiled or derived from the classified lines. Of course, many more papers were read than were actually used in the compilation. A selection of data was made that, in our judgment, represents the most accurate and reliable available. After a preliminary compilation for all ions was carried out, we returned to CrI to check the level values, review and incorporate any new papers that had appeared in the meantime, and prepare CrI text. This retracing was continued through all of the ions. A final check for new data was made on June 30, 1976, at which time the compilations were considered completed. The text for each ion is not a complete review of the literature but is intended to credit the major contributions.

## 2. Acknowledgments

Throughout this work we have made extensive use of the bibliographical files and reprint collection maintained in the Atomic Energy Levels Data Center by Dr. Lucy Hagan. Our thanks are extended to her for her generous cooperation. The compilation has also benefited greatly from the preprints that were generously provided by many of our colleagues.

We would like to thank Dr. W. C. Martin for many helpful discussions.

This work was carried out with the partial support of the U.S. Energy Research and Development Administration.

## Cr I

Z = 24

Ground state:  $1s^2 2s^2 2p^6 3s^2 3p^6 3d^5 4s^2 S_3$ 

The energy levels are from Kiess (1953) who remeasured the entire spectrum and extended the earlier work of Catalan and Sancho (1931) and a number of other investigators. The bulk of the *g*-factors for the levels are obtained from Catalan and Sancho and are supplemented by those of Kiess, which were given to three decimal places. The four place *g*-factors for  $3d^5(6S)4p\ ^7P_3$  and  $^7P_4$  were measured in an atomic beam by Budick, Goshen, and Marcus (1964).

Using the  $3d^5ns$  and  $3d^5np$  series of three to five Rydberg terms Kiess derived the ionization energy with an estimated uncertainty of  $\pm 2 \text{ cm}^{-1}$ .

The alphabetic prefixing of terms with lower case letters for distinguishing repeating terms of the same type has been retained from Kiess except where the levels were reinterpreted by Roth (1970) on the basis of his theoretical treatment.

Roth has calculated the odd-parity configurations  $3d^5 4p$ ,  $3d^4 4s 4p$ , and  $3d^3 4s^2 4p$  with configuration interaction. His

Ionization energy =  $54570 \text{ cm}^{-1}$  (6.7659 eV)

percentage compositions and designation changes for the experimental levels are adopted here. Roth distinguished repeating terms of the  $3d^n$  core by the letters *a*, *b*, . . . rather than by seniority. The percentages include the sum of seniority states contributing to the term.

Percentages for the configuration  $3d^5 4s$  were taken from an ab initio calculation by Vizbaraitė, Kupliauskis, and Tutlys (1968).

## ASSOCIATION SEQUENCES

Ground state is  $2s^2 2p^6 3s^2 3p^6 3d^5 4s^2$ 

Z =

Ionization energy =  $133\ 060\ \text{cm}^{-1}$  (16.4975 eV)

Kiess (1951) carried out the principal analysis of the spectrum using his extensive measurements of wavelengths and Zeeman-effect data. Changes in several of his term designations for the  $3d^44p$  configuration suggested by Roth (1969) on the basis of theoretical calculations have been adopted here. For these terms the alphabetical prefixing by Kiess has been dropped.

The percentage compositions for  $3d^44p$  are by Roth. Repeating terms of the  $3d^4$  core are labeled in alphabetical order rather than by seniority. The percentages represent the sum of seniority states contributing the same core term. Shadmi, Oreg, and Stein (1968) have calculated the  $3d^5$ ,  $3d^44s$ , and

$3d^34s^2$  configurations but give percentages only for  $a^2H$  and  $b^2H$ , apparently the only highly mixed terms. No changes in designations were made except for the  $e^2G$  and  $e^2D$  terms.

The ionization energy was derived by Russell (1950) utilizing the two-member  $3d^4ns$  series.

## Cr III

Ti I isoelectronic sequence

Z=24

Ground state:  $1s^2 2s^2 2p^6 3s^2 3p^6 3d^4$   $^5D_0$ Ionization energy = 249 700 cm<sup>-1</sup> (30.96 eV)

The analysis was begun by White (1929) who found systems of triplet and quintet terms, which were later unified by Bowen (1937). F. L. Moore considerably augmented this work and provided his unpublished results to C. E. Moore (1952) for inclusion in her compilation. Ekberg (1976) has remeasured the spectrum and established 76 new levels while rejecting 26 of those found by Moore. We give the results of Ekberg and the  $3d^3(^4F)4d^5H$  term found by White (1929).

The percentage composition of the levels of  $3d^4$  are from Pasternak and Goldschmidt (1972). Shadmi, Caspi, and Oreg (1969) calculated  $3d^4$ ,  $3d^34s$ , and  $3d^24s^2$  with configuration interaction but gave percentages only for the highly mixed  $^3P$  terms of  $3d^34s$ , which are quoted here.

The composition of  $3d^34p$  is from Roth (1968). His percentages include the sum of seniority states contributing to the same core term.

The ionization energy was derived by Catalan and Velasco (1952) from the 2-member  $3d^3ns$  series.

Sc I isoelectronic sequence

Z=24

Ground state:  $1s^2 2s^2 2p^6 3s^2 3p^6 3d^3 \ ^4F_{3/2}$ Ionization energy =  $396\ 000\ \text{cm}^{-1}$  (49.1 eV)

The initial analysis was by White (1929) and was later extended by Bowen (1937). The compilation by C. E. Moore (1952) consists of the unpublished analysis by F. L. Moore. Ekberg (1973) reobserved the spectrum and greatly extended the analysis but reported no levels above  $211\ 574\ \text{cm}^{-1}$ . He found thirteen of Moore's levels to be false. In view of this we give the levels reported by Ekberg (1973) and omit the levels given by Moore only. The percentage compositions are from a fitted calculation by Poppe (1976).

The ionization energy is an extrapolated value by Lotz (1967).

Ca I isoelectronic sequence

Ground state:  $1s^2 2s^2 2p^6 3s^2 3p^6 3d^2$   ${}^3F_2$  $Z = 24$ Ionization energy = 560 200 cm<sup>-1</sup> (69.46 eV)

The initial analysis is due to White (1929) who reported levels of the  $3d^2$ ,  $3d4s$ ,  $3d4p$ , and  $3d4d$  configurations. Additions and revisions were made by Cady and Edlén and were communicated to Moore for inclusion in her AEL compilation (1952). The spectrum was completely reobserved by Ekberg (1972) whose results are quoted here. He added the  ${}^1S_0$  level of  $3d^2$  and all the known levels of  $3d4d$  and  $3d5s$ . The one term of  $3d4d$  due to White was found to be false.

The ionization energy was derived by Ekberg from the series  $3d4s$  and  $3d5s$  with an estimated uncertainty of 0.04 eV.

K<sub>1</sub> isoelectronic sequence $Z = 24$ Ground state:  $1s^2 2s^2 2p^6 3s^2 3p^6 3d^2 D_{3/2}$ 

The first known terms were found by Gibbs and White (1926, 1929) who reported the positions of the  $3p^6 3d^2 D$ ,  $4s^2 S$ , and  $4p^2 P^\circ$  terms. The  $n f^2 F^\circ$  series for  $n=5$  to 10 was identified by Alexander, Feldman, and Fraenkel (1965) and the missing  $4f^2 F^\circ$  by Gabriel, Fawcett, and Jordan (1965) who replaced the false levels of this term given earlier by Kruger and Weissberg (1937). The  $4p^2 P^\circ - 4d^2 D$  multiplet was found by Fawcett (1970). Observations of open  $3p^6$ -core configurations were first reported by Feldman and Fraenkel (1966) who identified the  $3p^6 3d - 3p^5 3d 4s$  transition array. Some of these lines were classified by Cowan (1967). Gabriel, Fawcett, and Jordan (1966) classified 6 lines of the  $3p^6 3d - 3p^5 3d^2$  group.

The spectrum was reobserved in the range of 400–2500 Å by Ekberg (1973). He interpreted a considerable number of new lines and verified the earlier work. His revisions of the

values for the known levels and his additions to the analysis are quoted here. The ionization energy is derived by Ekberg from the  $nh$  series with an estimated uncertainty of  $\pm 6 \text{ cm}^{-1}$ .

Ar I isoelectronic sequence

Z=24

Ground state:  $1s^2 2s^2 2p^6 3s^2 3p^6 \ ^1S_0$ Ionization energy = 1 291 900 cm<sup>-1</sup> (160.18 eV)

The levels are taken from an extensive analysis by Ekberg (1976). The few earlier identifications are referenced in his work. The designations and percentage composition for the levels are also from Ekberg. A value for the ionization energy of 1 291 900 (600) cm<sup>-1</sup> was derived by him by extrapolation.

The same value may be derived from the 3-member  $ns$  series.

Cl I isoelectronic sequence

Z=24

Ground state:  $1s^2 2s^2 2p^6 3s^2 3p^5 {}^2P^o_{3/2}$ Ionization energy = 1 490 000 cm<sup>-1</sup> (184.7 eV)

All the known levels are derived from transitions to the  $3s^2 3p^5 {}^2P^o$  ground term. Edlén (1937) identified lines originating from all levels of the  $3s^2 3p^4 4s$  configuration except for the  ${}^4P_{1/2}$ . Earlier, Weissberg and Kruger (1936) had reported lines from the  ${}^2P$  term of this configuration as well as from the  ${}^2S$  term of  $3s 3p^6$ . The transitions from  $3s^2 3p^4 3d$  were identified by Gabriel, Fawcett, and Jordan (1966) and by Fawcett and Gabriel (1966). Those from  $3s^2 3p^4 4d$  were given by Fawcett, Cowan, and Hayes (1972). Line identifications in the  $3p^4 4d - 3p^4 4f$  transition array were also given in this paper but cannot be used to derive energy levels because they do not combine with known levels.

The recent measurements of the  $3s^2 3p^5 - 3s 3p^6$  doublet by

Smitt, Svensson, and Outred (1976) are used to determine the ground term interval.

The ionization energy is an extrapolated value by Lotz (1967).

S I isoelectronic sequence

 $Z = 24$ Ground state:  $1s^2 2s^2 2p^6 3s^2 3p^4$   ${}^3P_2$ Ionization energy = 1 688 000 cm<sup>-1</sup> (209.3 eV)

Edlén (1937) provided the initial spectral classifications by identifying the  $3p^4$ – $3p^3 4s$  transitions. Both singlet and triplet levels were detected but not the connection between them.

Classifications in the  $3p^4$ – $3p^3 3d$  transition array were made by Gabriel, Fawcett, and Jordan (1965) and by Fawcett and Gabriel (1966). Some new measurements were later provided by Fawcett (1971) as well as two newly classified lines of this group. The  $3s 3p^5$  configuration was found by Fawcett (1970). Classified lines of the  $3p^4$ – $3p^3 4d$  and  $3p^3 3d$ – $3p^3 4f$  arrays were reported by Fawcett, Cowan, and Hayes (1972). The latter array could not be used to derive  $3p^3 4f$  levels because of the lack of transitions to known levels.

Smitt, Svensson, and Outred (1976) give improved measurements of the  $3s^2 3p^4$ – $3s 3p^5$  transitions. They also found the

intersystem line  ${}^3P_2$ – ${}^1P_1^\circ$  and identified the  ${}^1S_0$ – ${}^1P_1^\circ$  line. The relative positions of all the levels are therefore known.

The ionization energy is an extrapolated value by Lotz (1976).

P<sub>1</sub> isoelectronic sequence

Z = 24

Ground state: 1s<sup>2</sup>2s<sup>2</sup>2p<sup>6</sup>3s<sup>2</sup>3p<sup>3</sup> 4S<sub>3/2</sub>Ionization energy = 1 971 000 cm<sup>-1</sup> (244.4 eV)

The levels of 3s3p<sup>4</sup> are due to Smitt, Svensson, and Outred (1976) who gave improved measurements and additional classifications in the 3s<sup>2</sup>3p<sup>3</sup>-3s3p<sup>4</sup> array, previously interpreted by Fawcett and Peacock (1967) and by Fawcett (1970). The important 4S°-2P° forbidden lines of the 3s<sup>2</sup>3p<sup>3</sup> configuration, which unify the term systems, were identified by Feldman and Doschek (1976) in solar coronal spectra. Transitions from 3p<sup>2</sup>3d to the ground configuration were identified by Gabriel, Fawcett, and Jordan (1966), Fawcett, Gabriel, and Saunders (1967), and most completely by Fawcett (1970). Lines of the 3s<sup>2</sup>3p<sup>3</sup>-3s<sup>2</sup>3p<sup>2</sup>4s array were classified by Fawcett, Cowan, and Hayes (1972). These authors also identified lines arising from the 3p<sup>2</sup>4f configuration but the lower levels have not been determined.

The ionization energy was obtained by Lotz (1967) by extrapolation.

## Cr XI

Si I isoelectronic sequence

Z = 24

Ground state:  $1s^2 2s^2 2p^6 3s^2 3p^2$   ${}^3P_0$ Ionization energy = 2 184 000 cm<sup>-1</sup> (270.8 eV)

Fawcett (1970, 1971) gave the first interpretation of the  $3s^2 3p^2$ – $3s 3p^3$  array. The level values were later revised by Smitt, Svensson, and Outred (1976) on the basis of their more accurate measurements. The connection between the singlet and triplet systems results from this later work and from the solar coronal line at 3996.8 Å (air) identified by Jefferies (1969) as arising from the forbidden  ${}^1D_2$ – ${}^3P_2$  transition in  $3s^2 3p^2$ .

The levels of  $3s^2 3p 3d$  are from Fawcett (1971). Those of  $3s^2 3p 4s$  and  $3s^2 3p 4d$  are due to Fawcett, Cowan, and Hayes

(1972). In table I of this reference the line given as 98.48 Å must be changed to 99.48 Å to fit its classification.

The ionization energy was extrapolated by Lotz (1967).

All isoelectronic sequence

Z = 24

Ground state:  $1s^2 2s^2 2p^6 3s^2 3p\ ^2P_{1/2}$ Ionization energy = 2 404 000 cm<sup>-1</sup> (298.0 eV)

The  $3p-4d$  doublet was identified by Edlén (1936). Thirty years later new observations of this spectrum by Gabriel, Fawcett, and Jordan (1966) resulted in the discovery of the  $3p-3d$  doublet. The non-diagonal line of this multiplet was identified by Fawcett, Gabriel, and Saunders (1967) by means of a laser-produced plasma.

The  $^2P$  and  $^2D$  terms of the low-lying  $3s3p^2$  configuration were first reported by Fawcett and Peacock (1967) again utilizing a laser plasma. Fawcett (1970) revised the classification of the  $3s^2 3p\ ^2P^o - 3s3p^2\ ^2D$  multiplet and added the  $^2P^o - ^2S$  lines. He also reported the  $^4P - ^4S$  lines of the  $3s3p^2 - 3p^3$  array. The quartet term position relative to the doublet system is not observed or predicted and therefore cannot be included here.

Fawcett (1971) later revised the wavelengths of the  $3s^2 3p - 3s3p^2$  array from new plates taken with the theta pinch source. His value of 412.46 Å for the  $^2P_{3/2} - ^2D_{3/2}$  line is inconsistent with the  $^2P_{1/2} - ^2D_{3/2}$  principal line and was not used here. He also reported the  $3p-3d$  doublet of the same array. Calculated wavelengths enabled Fawcett, Cowan, Kononov, and Hayes (1972) to identify more lines from the theta

pinch spectrum. They classified the  $3d-4f$  doublet and several quartet transitions unconnected with the doublets.

The ground term  $^2P^o$  splitting is obtained from the solar coronal line 8153.8 Å classified by Jefferies (1969).

The value for the ionization energy was obtained by extrapolation by Lotz (1967).

Mg I isoelectronic sequence

 $Z = 24$ Ground state:  $1s^2 2s^2 2p^6 3s^2 1S_0$ Ionization energy = 2 862 000 cm<sup>-1</sup> (354.8 eV)

The  $3s^2 1S_0 - 3s4p^1P_1$  resonance line was identified by Edlén (1936). He also reported two unconnected triplet systems, one containing levels of  $3s3p$ ,  $3s4s$ ,  $3s4d$ , and  $3s5d$ , and the other  $3s3d$ ,  $3s4f$ , and  $3s5f$ . The analysis was resumed thirty years later by Fawcett, Gabriel, and Saunders (1967) who unified the triplets by discovering the  $3s3p^3P^o - 3s3d^3D$  multiplet. They also identified the resonance line  $3s^2 1S_0 - 3s3p^1P_1$ . An interpolated value for the position of  $3s3p^3P_1$  relative to the ground state was given by Ekberg (1971) and was adopted in the present compilation.

The analysis was extended to  $3p^2$  by Fawcett and Peacock (1967) who identified the  $3s3p^3P^o - 3p^2^3P$  multiplet. Fawcett (1970) later found the  $1S_0$  of  $3p^2$ , the  $1D_2$  of  $3s3d$  and all the levels of  $3p3d$  presently known.

The analysis was augmented by Fawcett, Cowan, Kononov, and Hayes (1972) with their identification of transitions from  $3s4f^1F_0$ ,  $3s4d^1D_2$ , and levels of  $3p4f$ . Some of the last group

are not connected to known levels and are therefore not used here.

Improved measurements of the  $3s3p^3P^o - 3s3d^3D$  multiplet were made by Fawcett, Cowan, and Hayes (1972). In addition, they reported the  $1D_2$  of  $3s3d$  and the  $1D_2$  of  $3p^2$ .

The ionization energy is an extrapolated value obtained by Lotz (1967).

Ground state:  $1s^2 2s^2 2p^6 3s\ ^2S_{1/2}$ Ionization energy = 3 098 500 cm<sup>-1</sup> (384.17 eV)

Edlén (1936) reported three independent systems of doublets:  $3s-np$ ,  $3p-nd$  (and  $3p-4s$ ), and  $3d-nf$ . These were unified by Fawcett and Peacock (1967) who identified the  $3s-3p$  and  $3p-3d$  doublets. This permitted us to determine the ionization energy from the three member of series with an estimated uncertainty of  $\pm 700$  cm<sup>-1</sup>. The remeasured  $3p-3d$  doublet by Fawcett, Cowan, and Hayes (1972) was used in the

present compilation. The  $2p^5 3s^2\ ^2P^o$  term was found by Feldman and Cohen (1967).

Ne I isoelectronic sequence

 $Z = 24$ Ground state:  $1s^2 2s^2 2p^6$   $1S_0$ Ionization energy =  $8\ 151\ 000\ \text{cm}^{-1}$  (1010.6 eV)

Only resonance lines are classified for this ion. Tyrén (1938) identified the lines due to the  $2s^2 2p^5 3s$ ,  $3d$  and  $4d$  as well as the  $2s 2p^6 3p$  levels. Swartz, Kastner, Rothe, and Neupert (1971) tentatively identified  $2s^2 2p^5 4s$ ,  $4d$ ,  $5d$ , and  $6d$ . They note that the identification of  $2s^2 2p^5 4s$  is doubtful; it is therefore omitted here. We obtained the  $jl$ -coupling designations for levels of the  $2p^5 nd$  configurations from a comparison with similar rare gas spectra.

Kastner, Behring, and Cohen (1975) identified transitions between  $2p^5 3p$  and  $2p^5 4d$  but there is no connection with known levels.

We derived the ionization energy from the  $2s^2 2p^5 (^2P_{3/2}) nd\ ^2[3/2]$ , series for  $n = 3, 4, 5$ . The  $n = 6$  term does not fit well to a series calculation. The estimated uncertainty in the series limit is  $\pm 5000\ \text{cm}^{-1}$ .

F I isoelectronic sequence

 $Z = 24$ Ground state:  $1s^2 2s^2 2p^5 \ ^2P_{3/2}$ Ionization energy = 8 850 000 cm<sup>-1</sup> (1097 eV)

Cohen, Feldman, and Kastner (1968) classified many lines of the  $2s^2 2p^5 - 2s^2 2p^4 3s$  and  $3d$  transition arrays. This work was revised and extended by Feldman, Doschek, Cowan, and Cohen (1973) who also included energy level values. Since they used only resonance lines to evaluate the levels, we derived new values from their list of classified lines. The ground term  $2s^2 2p^5 \ ^2P^o$  interval was obtained by Fawcett (1971) from his identification of the  $1s^2 2s^2 2p^5 - 1s^2 2s^2 2p^6$  doublet at  $\sim 100$  Å, in agreement with the value provided by Feldman et al. (1973) from much shorter wavelength data. We used the new measurements of these lines by Doschek, Feldman, Cowan, and Cohen (1974) in combination with the data of Feldman et al. (1973) to derive the levels.

The  $2s 2p^6 \ ^2S_{1/2} - 2s 2p^5 3s \ ^2P^o$  multiplet is from Feldman et al. (1973).

The ionization energy was obtained by extrapolation by Lotz (1967).

O I isoelectronic sequence

Z = 24

Ground state:  $1s^2 2s^2 2p^4$   ${}^3P_2$ Ionization energy = 9 560 000 cm<sup>-1</sup> (1185 eV)

The splitting of the ground term is known from the line classifications of Fawcett (1971) for the transitions  $2s^2 2p^4 - 2s 2p^5$ . The  ${}^4P^\circ$  term of the latter configuration is given relative to an estimated position of  $2s^2 2p^4$   ${}^1D_2$  by Edlén (1972). Doschek, Feldman, and Cohen (1973) classified the lines of the array  $2s^2 2p^4 - 2s^2 2p^3 3s$  but found no connection between the singlets and triplets. They also identified the  ${}^1S_0$  of  $2s^2 2p^4$ . The  $2s^2 2p^3 3d$  levels are due to Fawcett and Hayes (1975). The transition  $2s 2p^5$   ${}^1P^\circ - 2p^6$   ${}^1S_0$  was reported by Doschek, Feldman, Davis, and Cowan (1975).

The value for the ionization energy was derived by Lotz (1967) by extrapolation.

N I isoelectronic sequence

 $Z = 24$ Ground state:  $1s^2 2s^2 2p^3 \ ^4S_{3/2}$ Ionization energy =  $10\ 480\ 000\ \text{cm}^{-1}$  (1299 eV)

Four lines of the  $2s^2 2p^3$   $^2D$ – $2s 2p^4$  ( $^2P$ ,  $^2D$ ) multiplets were classified by Fawcett (1971). The analysis of this transition array was extended and partly revised by Doschek, Feldman, Cowan, and Cohen (1974). The position of the doublets relative to ground state is based on the estimated position of  $2s^2 2p^3$   $^3P_{1/2}$  by Fawcett (1975). The  $^2S_{1/2}$  of  $2s 2p^4$  was later reported by Feldman, Doschek, Cowan, and Cohen (1975). Fawcett and Hayes (1975) classified the resonance line arising from  $2s^2 2p^2$  ( $^3P$ )  $3d$   $^4P_{5/2}$  and observed the  $2s^2 2p^2$  ( $^1D$ )  $3d$   $^2F_{7/2}$  level of the doublet system. They also located the  $2p^5$  configuration from transitions to  $2s 2p^4$   $^2D$ . The  $^2D_{3/2}$ – $^2P_{3/2}$  line of this multiplet was reported by Doschek, Feldman, Davis, and Cowan (1975).

The ionization energy was obtained by Lotz (1967) by extrapolation.

C<sub>1</sub> isoelectronic sequence

Z = 24

Ground state: 1s<sup>2</sup>2s<sup>2</sup>2p<sup>2</sup>3P<sub>0</sub>Ionization energy = 11 260 000 cm<sup>-1</sup> (1396 eV)

All observed levels are due to the analysis of Feldman, Doschek, Cowan, and Cohen (1975). They did not find the connection between singlets and triplets. The predicted position of the 2s<sup>2</sup>2p<sup>2</sup>1D<sub>2</sub> level was given by Fawcett and Cowan (1975).

The value for the ionization energy was extrapolated by Lotz (1967).

Be I isoelectronic sequence

 $Z = 24$ Ground state:  $1s^2 2s^2 ^1S_0$ Ionization energy = 13 180 000 cm<sup>-1</sup> (1634 eV)

Widing (1975) classified the resonance line arising from  $2s2p$   $^3P_1$ . The  $^3P_0$  and  $^3P_2$  of  $2s2p$  are from the predicted fine structure splitting by Goldsmith, Oren, Crooker, and Cohen (1973). Fawcett and Hayes have identified two lines of the  $2s2p$   $^3P$ – $2s3d$   $^3D$  multiplet.

The ionization energy is extrapolated by Lotz (1967).

Li 1 isoelectronic sequence

 $Z = 24$ Ground state:  $1s^2 2s\ ^2S_{1/2}$ Ionization energy = 13 884 000 cm<sup>-1</sup> (1721.4 eV)

The  $2s-3p$ ,  $2p-3s$ , and  $2p-3d$  doublets were reported by Goldsmith, Feldman, Oren, and Cohen (1972). The  $2p$  levels were connected to the ground level by the identification of the  $2s-2p$  lines by Widing and Purcell (1976) in solar flare spectra. Aglitskii, Boiko, Pikuz, and Faenov (1974) confirmed the lines identified by Goldsmith et al. (1972) and added the  $2s-4p$  and  $2p-4d$  doublets.

We derived the ionization energy from the 2-4p Rydberg terms.

He I isoelectronic sequence

Z=24

Ground state:  $1s^2 \ ^1S_0$ Ionization energy = 60 350 000 cm<sup>-1</sup> (7482 eV)

The  $1s2p \ ^1\text{P}^\circ$  resonance transitions were identified by Swartz, Kastner, Rothe, and Neupert (1971) as an unresolved spectral feature at 2.20 Å. Wavelengths of the separate lines obtained from solar flare spectra were given by Neupert (1971). The agreement with the theoretical values calculated by Swartz et al. (1971) using the formulas of Doyle (1969) is within 0.01%.

The ionization energy was extrapolated by Lotz (1967).

H<sup>+</sup> isoelectronic sequence

Z=24

Ground state: 1s <sup>2</sup>S<sub>1/2</sub>Ionization energy = 63 675 300 cm<sup>-1</sup> (7894.79 eV)

The theoretical values calculated by Erikson for the terms of this hydrogen-like ion are so much superior to the observed values that we have quoted them (up to  $n=4$ ). The binding energy of the 1s electron is given with an uncertainty of  $\pm 200$  cm<sup>-1</sup>; the levels are given relative to this value. For comparison, the observed value of 2p <sup>2</sup>P<sub>1/2,3/2</sub>

reported by Swartz, Kastner, Rothe, and Neupert (1971) is 48 000 000 cm<sup>-1</sup>.
