# Evaluation of the Thermodynamic Functions for Aqueous Sodium Chloride from Equilibrium and Calorimetric Measurements below 154 °C

E. Colin W. Clarke and David N. Glew

Corporate Research and Development, Dow Chemical Canada Inc., Sarnia, Ontario, Canada N7T 7K7

A new weighted least-squares method is described which is generally applicable for the nonsubjective evaluation of the best set of thermodynamic functions from a given data set of equilibrium ( $\Delta G$ ) and calorimetric ( $\Delta H$ ,  $C_p$ ) measurements. The method, applied to model a wide range of 2428 measurements for the water–sodium chloride system between –21 and 154 °C, accurately represents all measurements within experimental error. The resulting model is used to predict the thermodynamic functions and their standard errors for aqueous sodium chloride up to 110 °C. Tables are given for freezing point, solubility, boiling point, osmotic and activity coefficients, vapor pressure, apparent molal relative enthalpy, partial molal relative enthalpies, integral heat of solution, specific heat, apparent molal heat capacity, partial molal heat capacities, apparent molal relative heat capacity, partial molal relative heat capacities, standard thermodynamic functions, and their changes for dissolution.

Key words: activity coefficients; aqueous NaCl solutions; boiling points; brine properties; critically evaluated data; enthalpy; freezing points; heat capacity; osmotic coefficients; sodium chloride–water system; solubility; thermodynamic properties; vapor pressure.

### Chronological List of Thermodynamic Symbols

$T$	Thermodynamic temperature, Kelvin	$G_1^\circ, H_1^\circ, C_{p,1}^\circ$	Standard molar (Gibbs energy, enthalpy, heat capacity) of water
$P$	Total pressure	$G_2^\circ, H_2^\circ, C_{p,2}^\circ, S_2^\circ$	Standard molal (Gibbs energy, enthalpy, heat capacity, entropy) of NaCl in water
$m$	Molality of NaCl, mol NaCl/(kg H <sub>2</sub> O)	$G_1^{\text{ex}}, L_1, J_1$	Partial molal (excess Gibbs energy, relative enthalpy, relative heat capacity) of water in solution
$M_1$	Gram-molar mass of water, 18.0152 g	$G_2^{\text{ex}}, L_2, J_2$	Partial molal (excess Gibbs energy, relative enthalpy, relative heat capacity) of NaCl in solution
$M_2$	Gram-molar mass of NaCl, 58.442 77 g	$G_\phi, L_\phi, C_{p,\phi}$	Apparent molal (excess Gibbs energy, relative enthalpy, heat capacity) of NaCl in solution
$n_1, n_2$	Moles of (water, NaCl) in system	$G_c, H_c, C_{p,c}, S_c$	Molar (Gibbs energy, enthalpy, heat capacity, entropy) of crystalline NaCl
$R$	Gas constant, 8.314 41 J mol <sup>-1</sup> K <sup>-1</sup>	$c_p$	Specific heat of water, Eqs. (56) and (57)
$\phi$	Practical osmotic coefficient	$A, A_k$	Debye-Hückel limiting slope for osmotic coefficient, parameters for Eq. (9)
$\gamma$	Ionic mean molal activity coefficient	$Q, B, C, D, E$	$T$ -dependent parameters for Eqs. (6)–(8)
$\theta$	Reference temperature, 298.15 K	$Q_k, B_k, C_k, D_k, E_k$	Model parameters, Eq. (10)
$G, H, C_p, S$	Total (Gibbs energy, enthalpy, heat capacity, entropy) of system	$v_{gk}, v_{hk}, v_{ck}$	Temperature variables for ( $G, H, C_p$ ) functions, Eqs. (11), (18), and (24)
$G^\circ, H^\circ, C_p^\circ, S^\circ$	Total (Gibbs energy, enthalpy, heat capacity, entropy) of system with components in their standard states	$\Delta H_d$	Integral heat of dilution
$G^{\text{id}}$	Total Gibbs energy for ideal solution system	$\Delta H_s$	Integral heat of solution
$G^{\text{ex}}, L, J$	Total (excess Gibbs energy, relative enthalpy, relative heat capacity) of system	$\Delta H_{\text{d}}$	Differential heat of solution
$G_1, H_1, C_{p,1}$	Partial molal (Gibbs energy, enthalpy, heat capacity) of water in solution	$\Delta G^\circ, \Delta H^\circ$	Standard molal (Gibbs energy, enthalpy) of solutions of NaCl
$G_2, H_2, C_{p,2}, S_2$	Partial molal (Gibbs energy, enthalpy, heat capacity, entropy) of NaCl in solution		

### Chronological List of Statistical Symbols

<i>N</i>	Total number of data used, 2428	<i>n<sub>i</sub></i>	<i>j</i> of set <i>i</i>
<i>p</i>	Total number of parameters used, 35	<i>WS<sub>i</sub>, V<sub>i</sub></i>	Number of data in data set <i>i</i>
<i>t</i> value	Absolute value divided by standard error	$\delta_i^2$	(Set weight, variance) of data set <i>i</i>
<i>W<sub>ij</sub>, WI<sub>ij</sub></i>	(Weight, internal weight) of datum <i>j</i> in data set <i>i</i>	<i>s<sub>i</sub>, s( )</i>	Mean squared deviation for datum of unit weight in data set <i>i</i>
<i>WM</i>	Weight factor, function of molality	$\bar{\delta}_i, \bar{\delta}( )$	Estimate of standard error for datum with unit weight of [data set <i>i</i> , data type ( )]
<i>m<sub>L</sub>, m<sub>U</sub></i>	(Lower, upper) limit of molality for uniform error	$\bar{w}_i$	Mean bias of [data set <i>i</i> , data type ( )]
<i>F</i>	Weight factor, function of temperature, etc.	$\delta\phi, \delta\gamma, \delta L_d$	Mean internal weight of datum in data set
<i>Y<sub>ij</sub>, Ŷ<sub>ij</sub>, δ<sub>ij</sub></i>	(Observed value, calculated value, residual) of dependent variable for datum	$\delta\phi/\sigma\phi, \delta\gamma/\sigma\gamma$	Deviation of literature ( $\phi, \gamma, L_d$ ) values from model estimates
			Relative deviation of literature ( $\phi, \gamma$ ) values from model in standard errors

### 1. Introduction

Water is the world's most essential and abundant liquid. Common salt is the most abundant dissolved electrolyte in ocean water, and from the seas of antiquity are derived the very extensive rock salt deposits which occur worldwide. The continuous expansion of our industrial civilization since 1850 is directly correlated<sup>1,2</sup> with the increased commercial/technological use of salt by the ever evolving chemical industry. Presently, more than one-half of all the salt used is produced as liquid sodium chloride brine by solution mining.<sup>138,139</sup>

Thus it is inevitable that water is the prototype liquid solvent of science and industry, rock salt the prototype crystalline ionic solid, and liquid sodium chloride brine the prototype aqueous strong electrolyte solution. Water and salt are now readily prepared in their pure states on both large and small scales. As a consequence, modern scientific literature contains many independent experimental studies<sup>18-57,60-113,121-125</sup> including numerous and deviant equilibrium and calorimetric measurements of the sodium chloride-water system at low pressures and below the normal boiling point. Measurements are particularly numerous for dilute solutions at atmospheric pressure near ambient temperature.

It is now both appropriate and timely to organize and evaluate this large and disparate data base of experimental measurements to obtain reliable thermodynamic functions for aqueous sodium chloride at all compositions between saturation pressure and atmospheric pressure for temperatures up to 110 °C.

It is now particularly essential that there be available for sodium chloride brine—the foremost strong electrolyte solution of commerce, science, and technology—reliable values of thermodynamic functions which accurately represent the numerous measurements near and below 25 °C.

#### 1.1. Earlier Models and Tabulations

In 1945, in a classic paper, Robinson<sup>1</sup> combined his isopiestic measurements for sodium chloride at 25 °C with critically chosen literature values for vapor pressures,<sup>30,33,34,49-52</sup> electrochemical cell emfs,<sup>53,54,60-63</sup> freezing points,<sup>19</sup> and heats of dilution.<sup>75</sup> The data were treated by graphical methods to give self-consistent values, in the

Gibbs-Duhem sense, for the practical osmotic coefficient ( $\phi$ ) and for the stoichiometric mean molal ionic activity coefficient ( $\gamma$ ) for sodium chloride molality between 0.1 and 6.0*m*<sup>a</sup> at 25 °C. Robinson's values are often used for calibration and are so highly regarded that they have been published unchanged in 1955 and 1959 and again reprinted up to 1970.<sup>3</sup>

Harned and Owen<sup>2</sup> gave a critical account of the treatment of electrochemical cell emf measurements<sup>60-63</sup> to determine the activity coefficient of sodium chloride. Smith and Hirtle<sup>27</sup> combined their boiling point data<sup>26,27</sup> with activity coefficients from cell measurements<sup>61,62</sup> to evaluate  $\phi$  and  $\gamma$  of sodium chloride from 0.1 to 4.0*m* from 0 to 100 °C. Values derived for the partial molal relative enthalpy of sodium chloride ( $L_2$ ) and its temperature derivative ( $J_2$ ) were shown to be in satisfactory agreement with calorimetric heat of dilution<sup>75</sup> and heat capacity<sup>98</sup> measurements.

In an extensive review of thermal properties of aqueous uni-univalent electrolytes, Parker<sup>4</sup> critically evaluated the calorimetric determinations of aqueous sodium chloride heat capacity, integral heat of dilution ( $\Delta H_d$ ), and integral heat of solution ( $\Delta H_s$ ). Best values were tabulated for the apparent molal heat capacity ( $C_{p,\phi}$ ) from 15 to 30 °C and up to 6.17*m* at 25 °C; for the apparent molal heat capacity at infinite dilution ( $C_{p,\phi}^\circ$ ) from 15 to 30 °C; for the apparent molal relative enthalpy ( $L_\phi$ ) up to 6.17*m* at 25 °C; for  $L_2$  up to 5.84*m* at 25 °C; and for the heat of solution at infinite dilution ( $\Delta H_s^\circ$ ) at 25 °C.

In an evaluation of the osmotic and activity coefficients of uni-univalent electrolytes at 25 °C, Hamer and Wu<sup>5</sup> used as smoothing functions the classical Deybe-Hückel equations with an ion-size parameter,<sup>2,3</sup> together with virial terms  $Bm$ ,  $Cm^2$ , and  $Dm^3$ , as recommended by Lietzke and Stoughton.<sup>13</sup> Although considerable literature was quoted, NaCl was not underlined in their Table 6.1; this indicated that their smoothed  $\phi$  and  $\gamma$  values for sodium chloride were derived entirely from fitting the data listed by Robinson and Stokes<sup>3</sup> (probably Appendix 8.3).

Gibbard, Scatchard, Rousseau, and Creek<sup>7</sup> determined the osmotic coefficients of aqueous sodium chloride using the static vapor pressure method from 1.0 to 6.0*m* and from

<sup>a</sup>An expression such as 6.0*m* indicates a solution whose molality (moles of sodium chloride per unit mass of water) has a value *m* = 6.0 mol/kg.

25 to 100 °C. Using the method of least squares their measurements were combined with other  $\phi$  data<sup>19,21,22,30,34,38,41,43</sup> and with Parker's<sup>4</sup> tabulated enthalpy and heat capacity values at 25 °C to evaluate a 20-parameter representative model. The osmotic coefficient was represented as a function of molality by the classical Debye-Hückel function<sup>2,3</sup> with temperature-invariant ion-size parameter equal to 1.5 and four virial parameters in higher order terms of the type  $Bm$ ,  $Cm^2$ ,  $Dm^3$ , and  $Em^4$ . The temperature dependence of  $B$  (also of  $C$ ,  $D$ ,  $E$ , and of the Debye-Hückel limiting slope) was expressed by a five-parameter equation, mathematically equivalent to those earlier recommended<sup>5</sup> for the temperature dependence of  $\ln K_p$ . Of the 20 parameters ( $B_0, B_1, B_2, B_3, B_4, C_0-C_4, D_0-D_4, E_0-E_4$ ), the four enthalpy parameters ( $B_1, C_1, D_1, E_1$ ) were determined from values<sup>4</sup> of  $L_\phi$  at 25 °C, the four heat capacity parameters ( $B_2, C_2, D_2, E_2$ ) from values<sup>4</sup> of  $(C_{p,\phi} - C_{p,0})$  at 25 °C, while the remaining 12 parameters were determined from an unweighted least-squares treatment of the osmotic coefficients. The 251  $\phi$  measurements used in the regression were assigned equal unit weight, despite the fact that they were from nine different data sets using different methods and equipment over different temperature regions.

Calculated values were given for  $\phi$ ,  $\gamma$ ,  $L_\phi$ , and  $(C_{p,\phi} - C_{p,0})$  of sodium chloride from 0.1 to 6.0 m between 0 and 200 °C. Although the authors<sup>7</sup> found that the  $\phi$  data taken as a whole were well represented by their model, the freezing point data sets<sup>19,21,22</sup> were clearly not well represented, the residuals being systematic and several times larger than their real experimental errors. The calculated  $L_\phi$  values above 50 °C did not agree well with the heat of dilution measurements of Ensor and Anderson<sup>79</sup> or Messikomer and Wood,<sup>83</sup> the deviations being almost an order of magnitude larger than the calorimetric experimental errors.

In 1973, Pitzer<sup>8</sup> proposed a new empirical equation for improved representation of the thermodynamic properties of aqueous electrolytes at all concentrations. The osmotic coefficient was represented as a function of molality by a modified Debye-Hückel term,  $-Am^{1/2}(1+1.2m^{1/2})^{-1}$ , with limiting slope  $A$ , together with three other parameters in higher order terms of the type  $Qm e^{-2m^{1/2}}$ ,  $Bm$ , and  $Cm^2$ . The parametrically linear three-parameter equation for  $\phi$  and its Gibbs-Duhem analogue for  $\ln \gamma$  were critically tested and shown to give a proper representation of the osmotic and activity coefficients for an extensive range of single and mixed<sup>9</sup> aqueous electrolytes at 25 °C. To represent the thermodynamic properties of aqueous sodium chloride, Sylvester and Pitzer<sup>10,11</sup> extended the equations to include solution enthalpies and heat capacities, in addition to the osmotic and activity coefficients over a wide range of temperature. The temperature dependence of  $B$ ,  $C$ , and  $Q$  was represented, respectively, by five-, four-, and five-parameter equations (of type earlier recommended<sup>5</sup> for  $\ln K_p$ ) with the parameters for  $B$  equivalent to  $(B_0, B_1, B_2, B_3, B_4)$ , those for  $C$  equivalent to  $(C_0, C_1, C_2, C_3)$ , and those for  $Q$  equivalent to  $(Q_0, 0, 0, Q_3, Q_4)$  with  $Q_1$  and  $Q_2$  suppressed to zero. The thermodynamic properties of the solute at infinite dilution were represented by a four-parameter polynomial in  $T$ . Of the 16 undetermined parameters in their model, the three Gibbs energy

parameters ( $Q_0, B_0, C_0$ ) had been determined earlier<sup>8,9</sup> from the osmotic coefficients<sup>3</sup> at 25 °C, while the remaining 13 parameters were determined from a weighted least-squares treatment of an extensive array of 21 data sets at temperatures up to 300 °C. More recently, Pitzer, Bradley, Rogers, and Peiper<sup>12</sup> have given an improved treatment of aqueous sodium chloride properties for 974 data between 0 and 300 °C. A substantially modified model was used containing five adjustable constants and 30 parameters determined by a weighted least-squares treatment. The model excluded freezing point measurements at low temperature and contained a discontinuity at 255 K (-18.15 °C).

After completion of the present work, Pitzer, Peiper and Busey<sup>136</sup> published a new model for aqueous sodium chloride properties up to 100 MPa pressure and 300 °C. The model fitted 1227 data using two adjustable constants and 25 parameters for the low-pressure properties and an additional 28 parameters for the effects of pressure.

## 1.2. Present Objective

Earlier key evaluations<sup>1,2,4,6-12,136</sup> of the thermodynamic properties of aqueous sodium chloride have been reviewed briefly. It is the purpose of this work to provide an adequate, significant, and accurate representation of the wide variety and numerous equilibrium and calorimetric measurements for the water-sodium chloride system in the temperature range -22 to 154 °C. In particular, we wish (i) to describe a new, objective, and general technique for combining a variety of thermodynamic measurements of different types, from different sources and of different accuracies using the method of weighted least squares to give the best representative model, (ii) to apply the technique to represent 2428 sodium chloride measurements from 94 data sets<sup>1,18-57,60-113,121-125</sup> to within their various experimental errors, and (iii) to provide the best unbiased estimates for the values and standard errors for the thermodynamic functions of aqueous sodium chloride at all concentrations between 0 and 110 °C.

In contrast with earlier studies<sup>7,10-12,136</sup> which provide only estimates of the model parameters and of the derived thermodynamic properties, the present study additionally evaluates the propagation of errors from the lack of fit of the experimental measurements by the model, through the variances and covariances of the model parameters, thence to provide estimates of the standard errors on the derived thermodynamic properties. Thus during our model development, the statistical significance of each added parameter was tested<sup>118</sup> to justify its inclusion in the model. Finally, our estimates of the thermodynamic properties and their standard errors quantitatively reflect the best fit and the lack of fit, respectively, of the measurements by the model.

## 2. Definition of the Equations

### 2.1. Symbols and General Equations

Consider an aqueous solution system comprising 1 kg of water solvent (component subscript 1) and  $m$  moles of sodium chloride solute (component subscript 2) at constant total pressure  $P$  and at thermodynamic temperature  $T$ . The sodium chloride is taken as fully dissociated and  $M_1$  is the molar mass of water ( $18 \text{ g mol}^{-1}$ ) so that the system is com-

prised of  $n_1 = 1000/M_1$  moles of water together with  $n_2 = m$  moles of sodium chloride or  $2n_2$  moles sodium and chloride ions. For this system we define the total Gibbs energy, total enthalpy, and total heat capacity as  $G$ ,  $H$ , and  $C_p$ , respectively, and as  $G^\circ$ ,  $H^\circ$ , and  $C_p^\circ$  for the system with components in their standard states. The total Gibbs energy for the ideal solution  $G^{\text{id}}$  is defined by  $G^{\text{id}} = G^\circ + n_2 2RT(-1 + \ln m)$ . The total excess Gibbs energy, the total relative enthalpy, and the total relative heat capacity for the system are defined by  $G^{\text{ex}} = G - G^{\text{id}}$ ,  $L = H - H^\circ$ , and  $J = C_p - C_p^\circ$ , respectively.

In terms of the molar properties of the components we have

$$G^{\text{ex}} = n_1 G_1^{\text{ex}} + n_2 G_2^{\text{ex}} = n_2 G_\phi = n_2 2RT(1 - \phi + \ln \gamma), \quad (1)$$

$$L = n_1 L_1 + n_2 L_2 = n_1(H_1 - H_1^\circ) + n_2(H_2 - H_2^\circ) = H - H^\circ = n_2 L_\phi, \quad (2)$$

$$J = n_1 J_1 + n_2 J_2 = n_1(C_{p,1} - C_{p,1}^\circ) + n_2(C_{p,2} - C_{p,2}^\circ) = C_p - C_p^\circ = n_2(C_{p,\phi} - C_{p,2}^\circ), \quad (3)$$

where  $R$  is the molar gas constant,  $\phi$  is the practical osmotic coefficient of water,  $\gamma$  is the ionic mean molal activity coefficient of sodium chloride.  $G_1^{\text{ex}}$ ,  $L_1 = H_1 - H_1^\circ$ , and  $J_1 = C_{p,1} - C_{p,1}^\circ$  are the partial molal excess Gibbs energy, the partial molal relative enthalpy, and the partial molal relative heat capacity, respectively, of water;  $G_2^{\text{ex}}$ ,  $L_2 = H_2 - H_2^\circ$ , and  $J_2 = C_{p,2} - C_{p,2}^\circ$  are the corresponding partial molal functions of sodium chloride.  $G_\phi$ ,  $L_\phi$  and  $C_{p,\phi}$  are the apparent molal excess Gibbs energy, the apparent molal relative enthalpy, and the apparent molal heat capacity, respectively, of sodium chloride.  $C_{p,2}^\circ$  is the partial molal heat capacity of sodium chloride in the standard state and is identical with  $C_{p,\phi}^\circ$ , the apparent molal heat capacity of sodium chloride at infinite dilution.

For the system at constant pressure  $P$  and at constant molality  $m$ , the total functions  $G^{\text{ex}}$ ,  $L$ , and  $J$  in Eqs. (1)–(3) are related by the differential equations

$$\left[ \frac{\partial(G^{\text{ex}}/T)}{\partial(1/T)} \right]_{P,m} = L \quad (4)$$

and

$$\left\{ \frac{\partial[\partial(G^{\text{ex}}/T)/\partial(1/T)]}{\partial T} \right\}_{P,m} = (\partial L / \partial T)_{P,m} = J, \quad (5)$$

with similar relationships between the corresponding partial molal functions  $G_1^{\text{ex}}$ ,  $L_1$ , and  $J_1$ ;  $G_2^{\text{ex}}$ ,  $L_2$ , and  $J_2$ ;  $G_1$ ,  $H_1$ , and  $C_{p,1}$ ;  $G_2$ ,  $H_2$ , and  $C_{p,2}$ ;  $G_1^\circ$ ,  $H_1^\circ$ , and  $C_{p,1}^\circ$ ;  $G_2^\circ$ ,  $H_2^\circ$ , and  $C_{p,2}^\circ$ ; and between the three apparent molal functions  $G_\phi$ ,  $L_\phi$ , and  $(C_{p,\phi} - C_{p,2}^\circ)$  of sodium chloride.

## 2.2. Composition and Temperature Dependence of Model

In order to adequately represent the variation of the osmotic coefficient with molality  $m$  at fixed  $T$  we use an extended Pitzer-type<sup>8</sup> parametrically linear equation

$$\phi = 1 - Am^{1/2}(1 + 1.2m^{1/2})^{-1} + Qm e^{-2m^{1/2}} + Bm + Cm^2 + Dm^3 + Em^4, \quad (6)$$

in which  $A$  is the Debye-Hückel limiting slope for the osmotic coefficient<sup>8,14</sup> and  $Q$ ,  $B$ ,  $C$ ,  $D$ , and  $E$  are fitting parameters which are functions of  $T$  only.

The Gibbs-Duhem relation then gives the equivalent parametrically linear expression

$$\begin{aligned} \ln \gamma = & -A[m^{1/2}(1 + 1.2m^{1/2})^{-1} + (2/1.2)\ln(1 + 1.2m^{1/2})] \\ & + Q\frac{1}{2}[1 - (1 + 2m^{1/2} - 2m)e^{-2m^{1/2}}] \\ & + B\cdot2m + C\cdot\frac{3}{2}m^2 + D\cdot\frac{5}{3}m^3 + E\cdot\frac{1}{4}m^4 \end{aligned} \quad (7)$$

for the composition dependence of  $\gamma$  at  $T$ .

The variation of  $G_\phi$  with molality at  $T$  is given by the equation

$$\begin{aligned} G_\phi/RT = & -A(4/1.2)\ln(1 + 1.2m^{1/2}) \\ & + Q[1 - (1 + 2m^{1/2})e^{-2m^{1/2}}] \\ & + B\cdot2m + Cm^2 + D\cdot\frac{3}{2}m^3 + E\cdot\frac{1}{2}m^4, \end{aligned} \quad (8)$$

obtained by substituting Eqs. (6) and (7) into Eq. (1).

The temperature dependence of  $A$ , fully discussed elsewhere,<sup>14</sup> is properly represented between 0 and 154 °C by the five-parameter equation

$$A = \sum_{k=0}^4 A_k v_{gk}, \quad (9)$$

in which  $A_k$  are known parameters and  $v_{gk}$  are the temperature variables defined in Eq. (11). The temperature dependences of  $Q$ ,  $B$ ,  $C$ ,  $D$ , and  $E$  are represented by equations of the same type recommended earlier<sup>5</sup> for the temperature dependence of  $\ln K_p$ . These equations are

$$Q = \sum_{k=0}^7 Q_k v_{gk}, \quad (10a)$$

$$B = \sum_{k=0}^6 B_k v_{gk}, \quad (10b)$$

$$C = \sum_{k=0}^6 C_k v_{gk}, \quad (10c)$$

$$D = \sum_{k=0}^6 D_k v_{gk}, \quad (10d)$$

and

$$E = \sum_{k=0}^3 E_k v_{gk}, \quad (10e)$$

where the  $Q_k$ ,  $B_k$ ,  $C_k$ ,  $D_k$ , and  $E_k$  are invariant fitting parameters and the  $v_{gk}$  are temperature variables for Gibbs energy functions ( $\phi$ ,  $\ln \gamma$ , and  $\ln m_s$ ) and are defined by the relations

$$v_{g0} = (-1/\theta), \quad (11a)$$

and for  $k \geq 1$ ,

$$v_{gk} = \left[ \frac{\theta^{k-2}}{(k-1)!} x^k \sum_{n=1}^{\infty} \frac{n}{n+k-1} (-x)^{n-1} \right], \quad (11b)$$

in which  $x = (T - \theta)/\theta$ , and where, in this work, the reference temperature  $\theta = 298.15$  K.

## 2.3. Gibbs Energy Functions

The osmotic coefficient is represented as a function of  $m$  and  $T$  by the parametrically linear equation

$$\begin{aligned}\phi &= 1 - m^{1/2}(1 + 1.2m^{1/2})^{-1} \sum_{k=0}^4 A_k v_{gk} \\ &\quad + m e^{-2m^{1/2}} \sum_{k=0}^7 Q_k v_{gk} \\ &\quad + m \sum_{k=0}^6 B_k v_{gk} + m^2 \sum_{k=0}^6 C_k v_{gk} \\ &\quad + m^3 \sum_{k=0}^6 D_k v_{gk} + m^4 \sum_{k=0}^5 E_k v_{gk},\end{aligned}\quad (12)$$

obtained by substituting Eqs. (9) and (10) into Eq. (6).

The corresponding equation for the activity coefficient is

$$\begin{aligned}\ln \gamma &= -[m^{1/2}(1 + 1.2m^{1/2})^{-1} \\ &\quad + (2/1.2)\ln(1 + 1.2m^{1/2})] \sum_{k=0}^4 A_k v_{gk} \\ &\quad + \frac{1}{2}[1 - (1 + 2m^{1/2} - 2m)e^{-2m^{1/2}}] \sum_{k=0}^7 Q_k v_{gk} \\ &\quad + 2m \sum_{k=0}^6 B_k v_{gk} + \frac{3}{2}m^2 \sum_{k=0}^6 C_k v_{gk} \\ &\quad + \frac{4}{3}m^3 \sum_{k=0}^6 D_k v_{gk} + \frac{5}{4}m^4 \sum_{k=0}^5 E_k v_{gk},\end{aligned}\quad (13)$$

and that for the apparent molal excess Gibbs energy is

$$\begin{aligned}G_\phi/RT &= -(4/1.2)\ln(1 + 1.2m^{1/2}) \sum_{k=0}^4 A_k v_{gk} \\ &\quad + [1 - (1 + 2m^{1/2})e^{-2m^{1/2}}] \sum_{k=0}^7 Q_k v_{gk} \\ &\quad + 2m \sum_{k=0}^6 B_k v_{gk} + m^2 \sum_{k=0}^6 C_k v_{gk} \\ &\quad + \frac{2}{3}m^3 \sum_{k=0}^6 D_k v_{gk} + \frac{1}{2}m^4 \sum_{k=0}^5 E_k v_{gk}.\end{aligned}\quad (14)$$

#### 2.4. Apparent Molal Relative Enthalpy

The apparent molal relative enthalpy, defined by

$$L_\phi = \left[ \frac{\partial(G_\phi/T)}{\partial(1/T)} \right]_{P,m}, \quad (15)$$

is obtained by differentiating Eq. (14) with respect to  $1/T$  to give the parametrically linear equation

$$\begin{aligned}L_\phi/R &= -(4/1.2)\ln(1 + 1.2m^{1/2}) \sum_{k=0}^4 A_k v_{hk} \\ &\quad + [1 - (1 + 2m^{1/2})e^{-2m^{1/2}}] \sum_{k=0}^7 Q_k v_{hk} \\ &\quad + 2m \sum_{k=0}^6 B_k v_{hk} + m^2 \sum_{k=0}^6 C_k v_{hk} \\ &\quad + \frac{4}{3}m^3 \sum_{k=0}^6 D_k v_{hk} + \frac{1}{2}m^4 \sum_{k=0}^5 E_k v_{hk},\end{aligned}\quad (16)$$

in which  $v_{hk}$  are temperature variables for enthalpy functions ( $L_\phi/R$ ,  $\Delta H_d/R$ , and  $\Delta H_s/R$ ) defined by the relationship

$$v_{hk} = d(v_{gk})/d(1/T), \quad (17)$$

and obtained by differentiating Eq. (11) with respect to  $1/T$  to give

$$v_{hk} = 0, \quad (18a)$$

and for  $k \geq 1$ ,

$$v_{hk} = (-1)(T - \theta)^{k-1}/(k-1)! . \quad (18b)$$

#### 2.5. Heat Capacity Functions

The standard partial molal heat capacity of sodium chloride  $C_{p,2}^\circ$  is a function of temperature only and is represented as a Taylor's series expansion about reference temperature  $\theta$  by the expression

$$\begin{aligned}C_{p,2}^\circ &= (C_{p,2}^\circ)_\theta + (dC_{p,2}^\circ/dT)_\theta (T - \theta) + (d^2C_{p,2}^\circ/dT^2)_\theta \\ &\quad \times \frac{1}{2}(T - \theta)^2 + (d^3C_{p,2}^\circ/dT^3)_\theta \frac{1}{3}(T - \theta)^3 \\ &\quad + (d^4C_{p,2}^\circ/dT^4)_\theta \frac{1}{24}(T - \theta)^4 \\ &\quad + (d^5C_{p,2}^\circ/dT^5)_\theta \frac{1}{120}(T - \theta)^5\end{aligned}\quad (19)$$

or

$$C_{p,2}^\circ = \sum_{k=2}^7 (d^{k-2} C_{p,2}^\circ / dT^{k-2})_\theta [1/(k-2)!](T - \theta)^{k-2}, \quad (20)$$

in which the six parameters with subscript  $\theta$  are the temperature derivatives of  $C_{p,2}^\circ$  at  $\theta$ .

The apparent molal heat capacity of sodium chloride  $C_{p,\phi}$  is defined by the relation

$$C_{p,\phi} = C_{p,2}^\circ + (\partial L_\phi / \partial T)_{P,m} \quad (21)$$

and is obtained from Eq. (20) and the temperature derivative of Eq. (16) to give the parametrically linear equation

$$\begin{aligned}C_{p,\phi}/R &= \sum_{k=2}^7 (-1/R)(d^{k-2} C_{p,2}^\circ / dT^{k-2})_\theta v_{ck} \\ &\quad - (4/1.2)\ln(1 + 1.2m^{1/2}) \sum_{k=0}^4 A_k v_{ck} \\ &\quad + [1 - (1 + 2m^{1/2})e^{-2m^{1/2}}] \sum_{k=0}^7 Q_k v_{ck} \\ &\quad + 2m \sum_{k=0}^6 B_k v_{ck} + m^2 \sum_{k=0}^6 C_k v_{ck} \\ &\quad + \frac{4}{3}m^3 \sum_{k=0}^6 D_k v_{ck} + \frac{1}{2}m^4 \sum_{k=0}^5 E_k v_{ck},\end{aligned}\quad (22)$$

in which  $v_{ck}$  are temperature variables for heat capacity functions defined by the relationship

$$v_{ck} = d(v_{hk})/dT \quad (23)$$

and obtained by differentiating Eq. (18) with respect to  $T$  to give

$$v_{c0} = v_{c1} = 0 \quad (24a)$$

and for  $k \geq 2$

$$v_{ck} = (-1)(T - \theta)^{k-1}/(k-1)! \quad (24b)$$

## 2.6. Integral Heat of Dilution

The integral heat of dilution  $\Delta H_d(m_1 \rightarrow m_2)$  is the enthalpy change per mole of sodium chloride for dilution from initial state molality  $m_1$  to final state molality  $m_2$ , and is given by

$$\Delta H_d(m_1 \rightarrow m_2) = L_\phi(m_2) - L_\phi(m_1), \quad (25)$$

where  $L_\phi(m_2)$  and  $L_\phi(m_1)$  refer to Eq. (16) with  $m$  replaced by  $m_2$  and  $m_1$ , respectively. We take  $m_2 = 0$ , for which  $L_\phi(m_2) = 0$  and drop the subscript on  $m_1$  so that Eq. (25) becomes

$$\Delta H_d(m \rightarrow 0) = -L_\phi(m) \quad (26a)$$

which is abbreviated to read

$$\Delta H_d = -L_\phi, \quad (26b)$$

where  $\Delta H_d$  is the integral heat of dilution from molality  $m$  to infinite dilution and  $L_\phi$  is defined by Eq. (16).

## 2.7. Heat of Solution Functions

The integral heat of solution at infinite dilution  $\Delta H_s^\circ$  is the enthalpy change for dissolution of 1 mole of crystalline sodium chloride in an infinite excess of pure water, defined by

$$\Delta H_s^\circ = H_2^\circ - H_c, \quad (27)$$

in which  $H_2^\circ$  is the standard partial molal enthalpy of sodium chloride in solution, and  $H_c$  is the standard molar enthalpy of crystalline sodium chloride. Since  $H_2^\circ$  and  $H_c$  are both functions of  $T$  only,  $\Delta H_s^\circ$  at  $T$  is properly represented by the relationship

$$\begin{aligned} \Delta H_s^\circ &= (\Delta H_s^\circ)_\theta + \sum_{k=2}^7 (\partial^{k-2} C_{p,2}^\circ / \partial T^{k-2})_\theta [1/(k-1)!] \\ &\quad \times (T-\theta)^{k-1} - \sum_{k=2}^4 (\partial^{k-2} C_{p,c}^\circ / \partial T^{k-2})_\theta \\ &\quad \times [1/(k-1)!](T-\theta)^{k-1}, \end{aligned} \quad (28)$$

where the fitting parameter  $(\Delta H_s^\circ)_\theta$  is the integral heat of solution at infinite dilution at  $\theta$ , the six  $C_{p,2}^\circ$  parameters are the same as in Eq. (20), and the other three parameters are the known temperature derivatives of  $C_{p,c}^\circ$  for crystalline sodium chloride at  $\theta$ .

The integral heat of solution  $\Delta H_s$  for dissolution of 1 mole of sodium chloride in water to form a solution of molality  $m$  is given by the equation

$$\Delta H_s = \Delta H_s^\circ + L_\phi, \quad (29)$$

where  $\Delta H_s^\circ$  is defined by Eq. (28) and  $L_\phi$  by Eq. (16). The resulting equation representing  $\Delta H_s$  as a function of  $m$  and  $T$  is the parametrically linear equation

$$\begin{aligned} \Delta H_s/R &= (\Delta H_s^\circ)_\theta (-1/R) v_{h1} \\ &\quad + \sum_{k=2}^7 (-1/R) (\partial^{k-2} C_{p,2}^\circ / \partial T^{k-2})_\theta v_{hk} \\ &\quad - \sum_{k=2}^4 (-1/R) (\partial^{k-2} C_{p,c}^\circ / \partial T^{k-2})_\theta v_{hk} \\ &\quad - (4/1.2) \ln(1 + 1.2m^{1/2}) \sum_{k=0}^4 A_k v_{hk} \\ &\quad + [1 - (1 + 2m^{1/2})e^{-2m^{1/2}}] \sum_{k=0}^7 Q_k v_{hk} \\ &\quad + 2m \sum_{k=0}^6 B_k v_{hk} + m^2 \sum_{k=0}^6 C_k v_{hk} \\ &\quad + \frac{2}{3}m^3 \sum_{k=0}^6 D_k v_{hk} + \frac{1}{2}m^4 \sum_{k=0}^5 E_k v_{hk}. \end{aligned} \quad (30)$$

The differential heat of solution  $\Delta H_{ds}$  is the enthalpy change per mole of sodium chloride dissolved in a solution of initial molality  $m_1$  to form a solution of final molality  $m_2$ , and is defined by the expression

$$\Delta H_{ds} = \Delta H_s^\circ + [m_2 L_\phi(m_2) - m_1 L_\phi(m_1)](m_2 - m_1)^{-1}, \quad (31)$$

where  $\Delta H_s^\circ$  is given by Eq. (28), and  $L_\phi(m_2)$  and  $L_\phi(m_1)$  are given by Eq. (16) with  $m_2$  and  $m_1$ , respectively, substituted for  $m$ . In the limit, as  $(m_2 - m_1) \rightarrow 0$ , Eq. (31) gives

$$\Delta H_{ds} = \Delta H_s^\circ + L_2, \quad (32)$$

where  $L_2$  is the partial molal relative enthalpy of sodium chloride at molality  $m = m_2 = m_1$ .

## 2.8. Solubility Equilibrium

The solubility molality  $m_s$  and activity coefficient  $\gamma_s$  for aqueous sodium chloride in equilibrium with crystalline salt is defined by the Gibbs energy equality

$$G_c = G_2^\circ + 2RT \ln m_s \gamma_s, \quad (33)$$

which is rearranged to give

$$-\Delta G_s^\circ = -(G_2^\circ - G_c) = 2RT \ln m_s \gamma_s, \quad (34)$$

where  $G_c$  is the standard molar Gibbs energy of crystalline salt and  $\Delta G_2^\circ$  is the standard molal Gibbs energy change for its dissolution in water. Since  $G_2^\circ$  and  $G_c$  are both functions of  $T$  only,  $\Delta G_s^\circ$  at  $T$  is properly represented<sup>5</sup> by the expression

$$\begin{aligned} -\Delta G_s^\circ/T &= (\Delta G_s^\circ)_\theta v_{g0} + (\Delta H_s^\circ)_\theta v_{g1} \\ &\quad + \sum_{k=2}^7 (\partial^{k-2} C_{p,2}^\circ / \partial T^{k-2})_\theta v_{gk} \\ &\quad - \sum_{k=2}^4 (\partial^{k-2} C_{p,c}^\circ / \partial T^{k-2})_\theta v_{gk}, \end{aligned} \quad (35)$$

in which the fitting parameter  $(\Delta G_s^\circ)_\theta$  is the standard molal Gibbs energy change for dissolution of crystalline salt in water at  $\theta$ , and the other parameters are defined in Eq. (28). The resulting equation representing  $\ln m_s$  as a function of  $T$  is

$$\ln m_s = -(1/2R) \Delta G_s^\circ/T - \ln \gamma_s, \quad (36)$$

where  $\Delta G_s^\circ$  is defined by Eq. (35) and  $\ln \gamma_s$  by Eq. (13) with  $m_s$  replacing  $m$  to give the parametrically linear equation

$$\begin{aligned}
 \ln m_s = & (1/2R)(\Delta G_s^\circ)_\theta v_{g0} + (1/2R)(\Delta H_s^\circ)_\theta v_{g1} + \sum_{k=2}^7 (1/2R)(d^{k-2}C_{p,2}^\circ/dT^{k-2})_\theta v_{gk} \\
 & - \sum_{k=2}^4 (1/2R)(d^{k-2}C_{p,c}/dT^{k-2})_\theta v_{gk} + [m_s^{1/2}(1+1.2m_s^{1/2})^{-1} + (2/1.2)\ln(1+1.2m_s^{1/2})] \sum_{k=0}^4 A_k v_{gk} \\
 & - \frac{1}{2} [1 - (1+2m_s^{1/2}-2m_s) e^{-2m_s^{1/2}}] \sum_{k=0}^7 Q_k v_{gk} - 2m_s \sum_{k=0}^6 B_k v_{gk} - \frac{3}{2}m_s^2 \sum_{k=0}^6 C_k v_{gk} \\
 & - \frac{4}{3}m_s^3 \sum_{k=0}^6 D_k v_{gk} - \frac{5}{4}m_s^4 \sum_{k=0}^5 E_k v_{gk}. \tag{37}
 \end{aligned}$$

### 2.9. Parameters in Model

In Table 1 we list the maximum number of fitting parameters available in our regression model to represent the various types of thermodynamic measurement as a function of composition and temperature. The first two columns indicate the type of measurement and its representative equation, respectively. The third column lists the number of standard state parameters for sodium chloride and includes the molal dissolution parameters  $(\Delta G_s^\circ)_\theta$  and  $(\Delta H_s^\circ)_\theta$  and the solution heat capacity derivative parameters  $(d^r C_{p,2}^\circ/dT^r)_\theta$ . Columns 4–8 list the number of parameters available for each of the virial terms and the final column gives the maximum number of fitting parameters in each representative equation.

### 2.10. Additional Thermodynamic Functions

Additional equations are now given for those thermodynamic properties for which values will be tabulated later for aqueous sodium chloride. For these equations, the upper limits for  $k$  are those of our final regression model with parameters given in Table 5.

The partial molal relative enthalpy of water is given by

$$\begin{aligned}
 (J_1/R)(1000/2M_1 n_2) = & +m^{1/2}(1+1.2m^{1/2})^{-1} \sum_{k=0}^4 A_k v_{hk} \\
 & -m e^{-2m^{1/2}} \sum_{k=0}^6 Q_k v_{hk} \\
 & -m \sum_{k=0}^5 B_k v_{hk} - m^2 \sum_{k=0}^5 C_k v_{hk} \\
 & -m^3 \sum_{k=0}^4 D_k v_{hk} - m^4 \sum_{k=0}^2 E_k v_{hk}. \tag{38}
 \end{aligned}$$

TABLE 1. Maximum number of parameters for fitting various types of data

Data type	Equation	$(\Delta G_s^\circ)_\theta$ , $(\Delta H_s^\circ)_\theta$ , $(d^r C_{p,2}^\circ/dT^r)_\theta$	$Q$	$B$	$C$	$D$	$E$	Total
$\phi$	(12)	0	8	7	7	7	6	35
$\gamma$	(13)	0	8	7	7	7	6	35

$C_p$	(22)	6	6	5	5	5	4	31
$\Delta H_s$	(30)	7	7	6	6	6	5	37
$m_s$	(37)	8	8	7	7	7	6	43

The partial molal relative enthalpy of sodium chloride is given by

$$\begin{aligned}
 L_2/R = & -[2m^{1/2}(1+1.2m^{1/2})^{-1} \\
 & +(4/1.2)\ln(1+1.2m^{1/2})] \sum_{k=0}^4 A_k v_{hk} \\
 & +[1-(1+2m^{1/2}-2m)e^{-2m^{1/2}}] \sum_{k=0}^6 Q_k v_{hk} \\
 & +4m \sum_{k=0}^5 B_k v_{hk} + 3m^2 \sum_{k=0}^5 C_k v_{hk} \\
 & +\frac{8}{3}m^3 \sum_{k=0}^4 D_k v_{hk} + \frac{5}{4}m^4 \sum_{k=0}^2 E_k v_{hk}. \tag{39}
 \end{aligned}$$

The partial molal relative heat capacity of water is given by

$$\begin{aligned}
 (J_1/R)(1000/2M_1 n_2) = & +m^{1/2}(1+1.2m^{1/2})^{-1} \sum_{k=0}^4 A_k v_{ck} \\
 & -m e^{-2m^{1/2}} \sum_{k=0}^6 Q_k v_{ck} \\
 & -m \sum_{k=0}^5 B_k v_{ck} - m^2 \sum_{k=0}^5 C_k v_{ck} \\
 & -m^3 \sum_{k=0}^4 D_k v_{ck} - m^4 \sum_{k=0}^2 E_k v_{ck}. \tag{40}
 \end{aligned}$$

The partial molal relative heat capacity of sodium chloride is given by

$$\begin{aligned}
 J_2/R = & -[2m^{1/2}(1+1.2m^{1/2})^{-1} \\
 & +(4/1.2)\ln(1+1.2m^{1/2})] \sum_{k=0}^4 A_k v_{ck} \\
 & +[1-(1+2m^{1/2}-2m)e^{-2m^{1/2}}] \sum_{k=0}^6 Q_k v_{ck} \\
 & +4m \sum_{k=0}^5 B_k v_{ck} + 3m^2 \sum_{k=0}^5 C_k v_{ck} \\
 & +\frac{8}{3}m^3 \sum_{k=0}^4 D_k v_{ck} + \frac{5}{4}m^4 \sum_{k=0}^2 E_k v_{ck}. \tag{41}
 \end{aligned}$$

The partial molal heat capacity of water is given by

$$C_{p,1} = J_1 + C_{p,1}^e \tag{42}$$

and that of sodium chloride by

$$C_{p,2} = J_2 + C_{p,2}^e \tag{43}$$

where  $J_1$  and  $J_2$  are defined by Eqs. (40) and (41), respectively,  $C_{p,2}^{\circ}$  by Eq. (20), and  $C_{p,1}^{\circ}$  by multiplying Eqs. (56) and (57) by  $M_1/1000$ .

### 3. Method of Data Treatment

#### 3.1. Preparation of the Input Data

All input data measurements<sup>18-57,60-113,121-125</sup> were corrected into accepted modern units.<sup>15-17</sup> Molalities mol sodium chloride per kg water were corrected to the 1971 atomic weight scale<sup>15</sup> with  $18.0152 = M_1$  for the gram molar mass of water and  $58.442\ 77 = M_2$  for sodium chloride. Temperatures were corrected<sup>16</sup> to the International Practical Temperature Scale of 1968, denoted IPTS-68, and the thermody-

namic temperature was  $T\ K = 273.15 + t\ ^\circ\text{C}$  IPTS-68. Heat capacities were corrected by the factor  $(dt\ ^\circ\text{C}\ \text{IPTS-48}/dt\ ^\circ\text{C}$  IPTS-68) and to IPTS-68. Energy values were converted to absolute joules and the molar gas constant was<sup>17</sup>  $R = 8.314\ 41\ \text{J mol}^{-1}\ \text{K}^{-1}$ .

Details of the data sets used in the regression analysis are given in Table 2, which lists the set name used to identify each data set, the type of thermodynamic property measured, the experimental method used, the number of measurements made, their composition range, their temperature range, and the reference.

In Table 2 the set name identifying the data set is abbreviated from the surnames of the authors. When authors have provided more than one type of measurement the resulting data sets are identified and treated separately.

In Table 2 the data type of thermodynamic property is denoted as follows:

$\phi$ —osmotic coefficient  
 $\gamma$ —activity coefficient  
 $m_s$ —solubility  
 $\Delta H_d$ —heat of dilution  
 $\Delta H_s$ —heat of solution  
 $C_p$ —heat capacity.

In Table 2 the experimental method is denoted as follows:

FP—freezing point depression of ice

BP—boiling point elevation

VP or DVP—vapor pressure lowering by static or dynamic methods, respectively

EMF or EMFW—electromotive force of concentration cells without or with transference, respectively

EMFS—electromotive force of single compartment cell with standard electrode

IP—isopiestic comparison

IP/VP or IP/DVP— isopiestic comparison with standards of known vapor pressure by static or dynamic methods, respectively

IP/EMF or IP/EMFW— isopiestic comparison with

standards of known osmotic coefficient derived from concentration cells without or with transport, respectively

IP/INT—integration of isopiestic data

DFN—diffusion

SOLY—solubility of crystalline sodium chloride

CAL or FCAL—batch or flow calorimetry, respectively

CALAQ—dissolution calorimetry into aqueous sodium chloride.

Water activities from measurements of FP,<sup>18-25</sup> BP,<sup>26-28,123,124</sup> VP and DVP,<sup>29-45</sup> and IP<sup>47-57</sup> were corrected, expressed as osmotic coefficients and represented by Eq. (12). Measurements of FP were converted to osmotic coefficients using Eq. (A1) of Scatchard *et al.*<sup>114</sup> Measurements of VP, DVP, IP/VP, and IP/DVP were corrected for the nonideality<sup>115</sup> of water vapor.

Sodium chloride activity coefficients from electrochemical cell measurements<sup>60-68</sup> were completely reevaluated as follows. Emfs from concentration cells without transference<sup>60,61,65,67</sup> were corrected to give values of  $\ln(\gamma_2/\gamma_1)$  which were represented by the difference of Eq. (13) for the two compartment molalities  $m_2$  and  $m_1$ . Emfs from concentration cells with transference<sup>62,63</sup> were corrected and reevaluated using several different equations and various numerical methods to yield concordant values of  $\ln(\gamma_2/\gamma_1)$  which were represented by the difference of Eq. (13). Emfs from single-compartment cells<sup>66,68</sup> were corrected and the values of  $\ln \gamma$  represented by Eq. (13).

Activity coefficients from integration of isopiestic measurements<sup>46</sup> were reexpressed as  $\ln(\gamma_2/\gamma_1)$  values which were represented by the difference of Eq. (13) for  $m_2$  and  $m_1$ , where  $m_1$  was  $0.1\text{m}$ .

Heat of dilution measurements<sup>73-84,121,122</sup> were represented by Eq. (25). Integral heats of solution<sup>85,88-97</sup> were represented by Eq. (30) and differential heats of solution<sup>82,86</sup> by Eq. (31).

Heat capacity measurements<sup>98-113,125</sup> were corrected, expressed as apparent molal heat capacities and represented by Eq. (22). Sodium chloride solubility measurements<sup>69-72</sup> were represented by Eq. (37).

Heats of solution and solubility measurements represented by Eqs. (30), (31), and (37) required the auxiliary values of the molar heat capacity and its temperature derivatives for crystalline sodium chloride at 298.15 K. These values are  $(C_{p,c})_0 = 50.08 \text{ J mol}^{-1} \text{ K}^{-1}$ ,  $(dC_{p,c}/dT)_0 = 2.737 \times 10^{-2} \text{ J mol}^{-1} \text{ K}^{-2}$ , and  $(d^2C_{p,c}/dT^2)_0 = -1.054 \times 10^{-4} \text{ J mol}^{-1} \text{ K}^{-3}$ , obtained by correcting and fitting the measurements of Leadbetter and Settatree<sup>116</sup> between 304 and 423 K together with a value at 200 K from Stull and Prophet.<sup>117</sup>

Each experimental measurement (input datum point) defined the variables of its own representative equation. The dependent or response variable was always the sum of the measurement and its Debye-Hückel term, together with additional terms for the heat capacity of crystalline sodium chloride in the case of heats of solution and solubilities not at 298.15 K. The number of independent variables was defined by the type of measurement and corresponded with the parameters in Table I. The full regression model contained a

maximum for 43 independent variables, the eight for the standard state parameters were functions of  $T$  only, the other 35 for the virial parameters were separable products of functions of  $m$  with functions of  $T$ . Variables for each measurement were evaluated in double-precision arithmetic and were stored and identified by data set name with intraset datum number. For example, D, DV, P + P 15 refers to the variables of datum 15 in set D, DV, P + P and is found in the original paper<sup>110</sup> to be the 15th measurement with  $C_{p,\phi} = -39.9 \text{ J mol}^{-1} \text{ K}^{-1}$  for 0.999 28m NaCl at 25 °C.

### 3.2. Weighting the Equations

Reliable values for the thermodynamic functions of aqueous sodium chloride from zero to saturation molality between -22 and 154 °C are estimated by evaluating the regression model which adequately, properly, and best represents both the composition and temperature dependence of the numerous equilibrium and calorimetric measurements available for the system. The best unbiased estimates of the thermodynamic functions are those provided by the properly weighted least-squares regression<sup>118,119</sup> of all valid literature measurements. The measurements should be widely founded in respect to data type, experimental method, composition range, and temperature range so that the adequacy and significance of the regression model parameters can be tested and realistic estimates obtained for the standard errors on the input measurements. The problem is how to evaluate the proper weight factor by which to multiply the representative equation of each measurement in the regression so that each weighted equation has the same variance and thus is equally probable. Our method is outlined as follows.

Each measurement (say, datum point  $j$  from data set  $i$ ) in the regression was represented by its characteristic equation multiplied by its weight factor  $W_{ij}$  in the formation of the normal equations. The value of  $W_{ij}$  depended on the data type, was inversely proportional to the presumed variance of the measurement, and provided a quantitative measure of its importance in the regression: for an accurate measurement, the equation was weighted by a large value for  $W_{ij}$ ; for an inaccurate measurement the equation was weighted (multiplied) by a small value for  $W_{ij}$ . Measurements of the same type by the same authors were treated together as a data set, within which the variances of the individual measurements were expected to be approximately equal or closely related. On this basis of experimental similitude the datum weight was defined by

$$W_{ij} = WS_i \times WI_{ij}, \quad (44)$$

where  $WS_i$  is a common external weight factor characteristic of data set  $i$ , and  $WI_{ij}$  is an individual internal weight factor characteristic of the relative importance (proportional to the inverse variance) of datum  $j$  within its set  $i$ . The values of  $WS_i$  for each data set were determined and optimized simultaneously, as described later, with the solution of the least-squares normal equations.

Within a given data set, the values of  $WI_{ij}$  were expect-

ed (i) all to be unity where the variances of the measurements were all equal, or (ii) to be proportional to the inverse of the variances due to molality and temperature effects or to other factors such as multiple determinations. Thus the internal weight  $WI_{ij}$  was further subdivided and defined by

$$WI_{ij} = WM \times F, \quad (45)$$

where  $WM$  is a weight factor dependent on the molality of the datum, and  $F$  is a weight factor usually, but not always, dependent on the temperature of the datum.

Consider the regression of a total number  $N$  of input measurements comprised of  $n_1$  from data set 1,  $n_2$  from set 2, ...,  $n_i$  from general set  $i$ , ..., and  $n_{94}$  from final set 94. Thus,

$$N = \sum_{i=1}^{94} n_i. \quad (46)$$

The representation of  $N$  measurements by a regression model with  $p$  parameters leaves  $(N - p)$  degrees of freedom for the residuals of the regression. General data set  $i$  contains  $n_i$  datum points which have variance  $V_i$  and set weight  $WS_i$ . General datum point  $j$  in set  $i$  has weight  $W_{ij}$ , internal weight  $WI_{ij}$ , observed value  $Y_{ij}$ , calculated value from regression model  $\hat{Y}_{ij}$ , and residual  $\delta_{ij}$ , given by

$$\delta_{ij} = Y_{ij} - \hat{Y}_{ij}. \quad (47)$$

The datum weight  $W_{ij}$  is given by Eq. (44) as the product of set weight  $WS_i$  and internal weight  $WI_{ij}$  of the datum within the set. For many data sets, the internal weights  $WI_{ij}$  are all unity, or alternatively they are functions of molality, temperature, and plurality such that the internally weighted squared residuals  $WI_{ij} \delta_{ij}^2$  have the same distribution (variance) for all  $j$  members of set  $i$ . The mean-squared deviation  $\delta_i^2$  for a datum of unit internal weight is given by

$$\delta_i^2 = \left( \sum_{j=1}^{n_i} WI_{ij} \delta_{ij}^2 \right) / n_i \quad (48)$$

for set  $i$ . An estimate of the variance  $V_i$  for set  $i$  equal to the square of the estimate of the standard error  $s_i^2$  is given by

$$V_i = s_i^2 = \left[ \left( \sum_{j=1}^{n_i} WI_{ij} \delta_{ij}^2 \right) / n_i \right] [N / (N - p)] \quad (49)$$

as the product of the internally weighted mean-squared deviation  $\delta_i^2$  and the correction for the number of degrees of freedom of the residuals. Thus  $s_i$  is an estimate of the standard error for a measurement of unit internal weight in set  $i$ . For each data set we define the set weight factor as

$$WS_i = [1/V_i] [N / (N - p)], \quad (50)$$

which rearranges to give the expression

$$WS_i \left[ \left( \sum_{j=1}^{n_i} WI_{ij} \delta_{ij}^2 \right) / n_i \right] = 1, \quad (51)$$

which is invariant and unity for all data sets. Multiplying Eq. (51) by  $n_i$  for set  $i$  gives

$$WS_i \sum_{j=1}^{n_i} WI_{ij} \delta_{ij}^2 = n_i, \quad (52)$$

and summing  $n_i$  over all data sets from  $i = 1$  to 94 gives

$$\begin{aligned} \sum_{i=1}^{94} WS_i \sum_{j=1}^{n_i} WI_{ij} \delta_{ij}^2 &= \sum_{i=1}^{94} \sum_{j=1}^{n_i} W_{ij} \delta_{ij}^2 \\ &= \sum_{i=1}^{94} n_i = N, \end{aligned} \quad (53)$$

so that the weighted mean-squared deviation is unity, and the same for each of the  $N$  datum points in the regression.

The bias of data set  $i$  relative to the regression model is given by the weighted mean deviation  $\bar{\delta}_i$  defined by

$$\bar{\delta}_i = \sum_{j=1}^{n_i} WI_{ij} \delta_{ij} / \sum_{j=1}^{n_i} WI_{ij}. \quad (54)$$

Positive bias indicates that the measurements as a set exceed their calculated values; negative bias that the calculated values from the model are more positive and larger than the measured values.

The mean internal weight of a measurement in data set  $i$ , denoted  $\bar{wi}_i$ , is defined by

$$\bar{wi}_i = \sum_{j=1}^{n_i} WI_{ij} / n_i. \quad (55)$$

The mean internal weight of a datum gives a measure of the relative goodness of the average measurement in the set compared with unit weight assigned to the good and reliable single measurement. A mean internal weight of unity shows all measurements equally good. A mean internal weight less than unity indicates the proportion and extent of experimentally prejudiced measurements within the data set. A mean internal weight of greater than unity indicates the number of replicate determinations per average input measurement.

### 3.3. Determination of the Weights

Initially the first weights  $W_{ij}$  for Eq. (44) were taken as unity for all measurements, and the first weighted normal equations were formed and solved to give the first regression model. This model was used to evaluate the first  $\hat{Y}_{ij}$  and through Eq. (47) the first residuals  $\delta_{ij}$  which were substituted into Eq. (51) to give the first set weights  $WS_i$ . At this point the first regression cycle was complete. The second cycle started using the first set weights  $WS_i$  in Eq. (44) with all  $WI_{ij}$  taken as unity to give the second weights  $W_{ij}^{(1)}$ , the second weighted normal equations were formed and solved to give the second regression model, and so on. A number of cycles were run to converge the data set weights  $WS_i$  so that Eq. (51) was true for all 94 data sets under conditions where all  $WI_{ij}$  were taken as unity.

At this stage the normalized residuals  $WI_{ij}^{1/2} \delta_{ij} / s_i$  were plotted on the line printer against molality and against temperature for each data set, and the graphs were examined to confirm a sensibly random distribution of residuals. In data sets where the residuals deviated significantly and systematically from randomness and where the measurement technique would lead us to expect a systematic effect for experimental reasons, internal weights  $WI_{ij}$  less than unity were applied to remove the systematic bias and make the internally weighted residuals,  $WI_{ij}^{1/2} \delta_{ij}$ , sensibly the same for all  $j$  measurements of data set  $i$ . The internal weights were applied by substituting  $WI_{ij}$  values in Eq. (44) and using extant

$WS_i$  values, a number of regression cycles were run to provide new converged values of  $WS_i$ . The resulting graphs of the normalized residuals were again examined to confirm a random distribution of weighted residuals. Data sets that still showed systematic deviations from randomness attributable to experimental effects were again internally weighted and the set weights  $WS_i$  were again converged. This process was continued until all data sets showed randomly distributed normalized residuals, so that all measurements were properly weighted and the resulting regression model was the unbiased estimator<sup>118,119</sup> of minimum variance of the input measurements.

Every effort was made to retain all 2444 input measurements within the regression by appropriate weighting. Those measurements that were found to lie more than three standard deviations from the model were reexamined and were

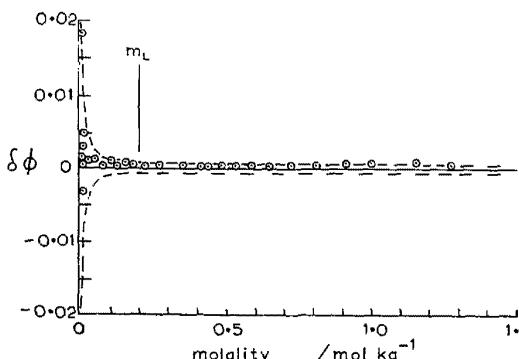

FIG. 1. The unweighted residuals  $\delta\phi$  of osmotic coefficients of data set S + P (Ref. 19) show increased variability of low molality. The dashed curves indicate the envelope of the standard error, which increases in magnitude at molalities less than  $m_L$  at 0.2 mol kg<sup>-1</sup>.

discarded only when they were also outliers from their own data set. This very conservative procedure resulted in the rejection of only 16 measurements from the regression and thereby reduced the risk of induced bias in the model.

In the final iteration cycle of the regression analysis, after all weight factors had been converged and were correct, the weighted equation for each of the input measurements had the same variance, was equally probable, and thus was properly weighted for the formation of the normal equations of maximum probability. The entries in Tables 3 and 4 summarize the final converged scheme of internal weights for the equations of 2428 measurements from 94 data sets.

Table 3 lists the data sets in which  $WI_{ij}$  was unity for each measurement: within a given set this implies that each datum  $j$  had the same variance and was equally reliable or probable. For small data sets without information on errors from the authors, we assumed  $WI_{ij} = 1.0$  for each datum, for the lack of any more correct weighting scheme. For large data sets, the graphs of the residuals plotted against molality and against temperature confirmed *a posteriori* that  $WI_{ij} = 1.0$  was a good approximation.

Table 4 lists the data sets with internal weights differing from unity. When authors gave assessments of experimental error, these were used together with the distribution of the residuals to define the internal weights for the set. Our assignment of nonunit internal weights was always conservative; if uncertain, we assigned unit internal weight. No internal weight differing from unity was ever assigned arbitrarily. All nonunit internal weights were assigned to reflect presumed real experimental effects, such as, (i) inadequate detector sensitivity for measurements at low molality and (ii) decrease of experimental accuracy for measurements at high or at low temperatures. Wherever possible, internal weights were assigned with values less than unity to leave most measurements in the set with unit internal weight; thus Table 4 indicates only those conditions where  $WM$  or  $F$  in Eq. (45) differed from unity.

For measurements of  $\phi$ ,  $\Delta H_d$ , and  $C_{p,\phi}$  the graphs of the unweighted residuals plotted against molality were found often to be bounded by envelopes similar to the dashed curves shown in Fig. 1. From high molality, the envelope of

residuals was sensibly parallel to the abscissa down to a lower limiting value, denoted  $m_U$ , below which it deviated sharply away from the axis, inversely proportional to  $m$ . The trumpet-shaped deviation contour at low  $m$  was to be expected from the definition of these thermodynamic properties, and arose because the experimental limits of signal detection had been reached. The values of  $m_L$  are listed in the second column of Table 4: for measurements with  $m > m_L$  we took  $WM = 1.0$  in Eq. (45); for those with  $m < m_L$  we took  $WM = (m/m_L)^2$ . For heats of dilution,  $m$  and  $m_L$  were the means of the initial and final state molalities, except for the data sets E + A<sup>79</sup> and M, H + H<sup>80</sup> for which it was more realistic to use the final state molalities. For the data sets in Table 4 with no value listed for  $m_L$ , the weight factor  $WM$  in Eq. (45) was unity for all measurements.

Two data sets only gave unweighted residuals which increased systematically with molality above an upper limiting value, denoted  $m_U$ . In the case of data set T<sup>67</sup> we took  $m_U = 0.1$  mol kg<sup>-1</sup>, and for set M + W,<sup>83</sup>  $m_U = 1.3$  mol kg<sup>-1</sup>; for measurements with  $m_L < m < m_U$ , we took  $WM = 1.0$  in Eq. (45); for measurements with  $m > m_U$ , we took  $WM = (m_U/m)^2$ .

The final three columns in Table 4 indicate the nonunit values of weight factor  $F$  in Eq. (45). For data set S,<sup>26</sup> we show  $F|_{60^\circ\text{C}} = 0.4$ , abbreviated from  $F(60^\circ\text{C}) = 0.4$ , meaning that each measurement at 60 °C had  $F = 0.4$ ; similarly, each measurement at 70 °C had  $F = 0.4$ . For set Y + M,<sup>76</sup>  $F = 0.011$  for measurements at 0.2 °C and  $F = 0.2$  for those at 12.6 °C. For set Y + V,<sup>74</sup> the data points Nos. 1 and 2, with atypically large dilution ratios, had  $F = 0.01$ . For set M, D + VH<sup>28</sup> datum No. 15 had  $F = 0.29$ . In set P + D,<sup>43</sup> all data were weighted; a measurement with molality  $m$  had weight  $F = m^2/2.1$ . In data sets C + C<sup>92</sup> and MR + W<sup>84</sup> the input measurements were mean values for  $r$  replicate determinations so that each measurement was weighted with  $F = r$ . The first entry for the composite data set S + L, I, CT indicates  $F = 0.01$  for measurements at and above 100 °C, evaluated by Linke<sup>70</sup>; the second entry indicates  $F = 0.25$  for measurements between 0 and 55 °C, evaluated by Brönsted<sup>69</sup>; the third entry shows  $F = 0.1$  for the two measurements at 125 and 150 °C from Liu and Lindsay.<sup>42</sup> For the data sets in Table 4 where  $F$  is not specified, its value in Eq. (45) was taken as unity.

### 3.4. Regression Model Parameters

Extensive significance testing of many models containing from 24 to 43 parameters was conducted to determine the minimum number and type of parameters required to provide an adequate and unbiased fit of all experimental measurements. We were concerned (i) not to overfit the data and follow false peaks and valleys between inaccurate and incompatible data sets by retaining too many and spurious parameters, and (ii) not to introduce bias by underfitting<sup>118,119</sup> and thereby improperly reproduce the real contours of the data by rejecting too many and significant parameters.

Tests indicated that the regression model with 43 pa-

TABLE 5. Regression model parameters and standard errors at 298.15 K

rameters and independent variables was probably overfitted, so that the highest order parameters with the smaller values of  $t$  ( $t$  = absolute value of parameter/standard error of parameter) were systematically rejected and the regression was reweighted, reconverged, and retested. This was repeated until a minimum set of parameters was obtained. The parameters rejected were  $Q_7$ ,  $B_6$ ,  $C_6$ ,  $D_6$ ,  $D_5$ ,  $E_5$ ,  $E_4$ , and  $E_3$ . Finally, we had rejected as many parameters of high order as possible, while retaining the ability of the model to represent the data sets without large increases in the estimates of the set variances. The adequacy of the regression model to fit the data depended predominantly on the conflict between measurements of various discordant data sets, not on the ability of the model to represent any particular set.

Table 5 lists the values found for the minimum-variance unbiased estimates of the 35 parameters and their standard errors at reference temperature  $\theta = 298.15$  K for our model of aqueous sodium chloride between -22 and 154 °C. Values of the parameters are given to seven figures to permit exact evaluation of derived functions; the standard errors are given to three figures. The parameters of highest order, namely  $(d^5 C_{p,2}^0/dT^5)_\theta / R$ ,  $Q_6$ ,  $B_5$ ,  $C_5$ ,  $D_4$ , and  $E_2$  have statistical  $t$  values of 7.9, 25, 13, 11, 7.9, and 13, respectively, indicating that the values of our least significant parameters,

$(d^5 C_{p,2}^0/dT^5)_\theta / R$  and  $D_4$ , could arise by chance at a probability level of about one in  $10^{15}$  times, and even less frequently for the values of the other four parameters. We note that all sets of parameters in Table 5 are complete and have no terms arbitrarily suppressed to zero, as required for a valid general Taylor's series representation of continuous Gibbs energy functions.<sup>5</sup>

The values and standard errors of the model parameters of highest order are independent of the value of reference temperature  $\theta$ , whereas the values and errors of all other lower order parameters depend on the value of  $\theta$ . As a result the size of the  $t$  value for parameter significance also depends on the value of  $\theta$  for all but the highest order parameters. To overcome this deficiency and to provide a more realistic  $t$  value we evaluate the mean absolute  $t$  value for each parameter for  $\theta$  varied over the data range -20 to 150 °C. A large mean  $t$  value indicates a well-defined parameter with relatively small error; a small mean  $t$  value indicates a poorly defined parameter. The final column of Table 7 presents the mean  $t$  values for the 35 parameters of our final regression model. The systematics of the  $t$  values are clearly apparent. The parameter sets in order of decreasing  $t$  values are  $\{\Delta G_s^0, \Delta H_s^0\} > \{C_{p,2}^0, \dots, (d^5 C_{p,2}^0/dT^5)\} > \{Q_0, \dots, Q_6\} > \{B_0, \dots, B_5\} > \{C_0, \dots, C_5\} > \{D_0, \dots, D_4\} > \{E_0, E_1, E_2\}$ ,

with the sets of standard-state parameters having greatest significance and the sets of the higher order virials having progressively less significance. Within a given parameter set the higher order temperature derivatives, denoted by the larger value subscripts, are usually of smaller significance. The zero order parameters,  $Q_0$ ,  $B_0$ ,  $C_0$ ,  $D_0$ , and  $E_0$  are Gibbs energy parameters and their  $t$  values reflect the accuracy of the equilibrium osmotic and activity coefficient measurements at progressively higher concentrations. The first order parameters  $Q_1$ ,  $B_1$ ,  $C_1$ ,  $D_1$ , and  $E_1$  are enthalpy parameters and the anomalously high  $t$  values of  $C_1$ ,  $D_1$ , and  $E_1$  reflect the numerous accurate calorimetric enthalpy measurements at higher concentrations. The second order parameters,  $Q_2$ ,  $B_2$ ,  $C_2$ ,  $D_2$ , and  $E_2$  are heat capacity parameters which reflect both the calorimetric heat capacity measurements and the first temperature derivatives of the enthalpy measurements. The parameters of third, fourth, and higher order are less significant than the first and second order parameters, and attest to the generally decreasing accuracy of the higher order temperature derivatives.

### 3.5. Partial Leverage of the Data

In the development and confirmation of our final weighted least-squares regression model we used the concept

of partial leverage<sup>127,128</sup> to define the influence of each of the 2428 measurements, each of the 94 data sets, and each of the three major data types (Gibbs energy, enthalpy, and heat capacity) on each of the 35 independent variables, and thus on the definition of the values of the 35 parameters. Each measurement defined up to 35 partial leverages, one for each independent variable used, so that (i) the sum of the partial leverages for a given independent variable over all 2428 measurements was unity and (ii) the sum of all partial leverages over all measurements was 35. A measurement with zero leverage had<sup>128</sup> no influence on the fit. A measurement with a leverage of unity indicated that one degree of freedom (one parameter) had<sup>128</sup> effectively been devoted to fitting the measurement.

In Table 6 we list the sums of the partial leverages for each data set in order of decreasing influence. The sum of partial leverages 5.12 for data set MR + W means that the heat of dilution measurements of Mayrath and Wood<sup>84</sup> are influential in determining effectively 5.12 parameters out of the total 35. This high leverage sum for set MR + W reflects (i) the large number of measurements in the set, (ii) that the measurements are located away from the means at both upper temperature and concentration limits, and (iii) that the measurements are very precise and have high weights. In contrast, and despite the high precision of Harned's<sup>84</sup> diffusion measurements, the low partial leverage sum for set

TABLE 6. Data sets ordered by sums of partial leverages

B, M + C	0.16				

H(DFN) reflects the small number of measurements in the set and the fact that the measurements are located near the mean temperature and are at low concentration. More generally, a low sum of partial leverages for a data set near the bottom of the list in Table 6 reflects a low set weight and the poor agreement between the data and the more influential data sets above it in the list.

The sum of the partial leverages for all  $\phi$  data is 4.90, for all  $\ln \gamma$  data is 0.88, for all solubility data is 1.74, for Gibbs energy data is 7.52 for heat of dilution data is 17.57, for heat of solution data is 1.04 for enthalpy data is 18.61, and for all heat capacity data is 8.87. The leverage and influence of the heat of dilution data is more than twice that of all Gibbs energy data and just less than twice that of all heat capacity data. The leverage and influence of the osmotic coefficient data is more than five times that of the activity coefficient data. The Gibbs energy data define the six Gibbs energy parameters  $[(\Delta G_s^0)/R, Q_0, B_0, C_0, D_0, \text{ and } E_0]$  and about two further parameters in the rest of the model.

In Table 7, we list the sums of the partial leverages for

TABLE 7. Influence of data type on parameters at 298.15 K

Parameter	Gibbs energy data	Enthalpy data	Heat capacity data	t value for $\theta$
degree of freedom	sum of partial leverages	sum of partial leverages	sum of partial leverages	-20 to 150 °C range

all Gibbs energy data (column 2), enthalpy data (column 3), and heat capacity data (column 4) for each of the independent variable functions for the 35 parameters at 25 °C. The sum of the three entries in each row is unity, corresponding to the complete definition of the one degree of freedom associated with each parameter. The magnitude of the entries provides a quantitative measure of which type of data influences and defines each parameter.

For the first six degrees of freedom, associated with the six Gibbs parameters, the Gibbs energy data give a partial leverage sum of 5.23, the enthalpy data give 0.68, and the heat capacity data 0.09, demonstrating the expected predominant influence of the Gibbs energy data on the definition of the Gibbs energy parameters.

For the second six degrees of freedom, associated with the enthalpy parameters  $[(\Delta H_s^0)/R, Q_0, B_0, C_0, D_0, \text{ and } E_0]$ , the enthalpy data provide an overwhelming influence with a sum of partial leverages of 5.65, the Gibbs energy data provide 0.23, and the heat capacity data provide 0.12.

For the third six degrees of freedom, associated with the heat capacity parameters  $[(C_{p,2}^0)/R, Q_2, B_2, C_2, D_2, \text{ and } E_2]$ , the enthalpy data provide a surprising partial leverage sum of 3.76, three times greater than for the heat capacity data (1.13) or the Gibbs energy data (1.11).

The heat of solution parameter  $(\Delta H_s^0)/R$  is defined more by the heat of dilution data with partial leverage sum of 0.51 than by the expected heat of solution data with leverage sum of 0.46. Similarly, the standard heat capacity parameter  $(C_{p,2}^0)/R$  is defined more by the enthalpy data with partial sum of 0.56 than by the expected heat capacity data with leverage sum of 0.42.

Solubility data provide the largest contributions to the Gibbs energy leverages for  $E_2, D_2, C_2$ , and  $B_2$ .

The virial parameter set  $E_0, E_1, E_2$  is almost completely defined by the Gibbs energy and enthalpy data with partial leverage sum of 2.94, with the heat capacity data contributing only 0.06; this occurs because the heat capacity data contain very few measurements at high concentration at both low and high temperatures.

The five degrees of freedom associated with the standard state temperature derivatives of heat capacity  $(dC_{p,2}^0/dT)/R$  to  $(d^5 C_{p,2}^0/dT^5)/R$  are determined more completely for the higher derivatives by the heat capacity data and less by the enthalpy data. The two parameters  $Q_5$  and  $Q_6$  reflect a similar influence.

On the contrary, the remaining ten degrees of freedom associated with parameters  $Q_3, B_3, C_3, D_3, Q_4, B_4, C_4, D_4, B_5$  and  $C_5$  are defined more by the extensive enthalpy data and less by the heat capacity data.

The temperature distribution of the sums of the partial leverages showed that 20 parameters were defined by (committed to) the fits of the measurements between 0 and 25 °C, compared with 14 parameters for all measurements at the higher temperatures above 25 °C. A minimum of 21 parameters was essential for a proper representation of the very rapidly varying low-temperature measurements below 25 °C. In test regression models containing fewer than the 35 parameters it was invariably the fits of the low-temperature measurements that were significantly prejudiced by the few-

er parameters. These findings concur with earlier studies<sup>7,10-12,136</sup> which discussed and showed the poorer fits to the measurements at lower temperatures.

### 3.6. Fit of the Model to the Measurements

The square of the multiple correlation coefficient for the model is  $R^2 = 0.999\ 943$ , which shows that 99.9943% of the variance of the input response variable is explained by the model, and that 0.0057% is the residual, unexplained

due to bias and error. The goodness of fit of the regression model (parameters in Table 5) to the measurements of data set  $i$  is quantitatively defined by the set weight  $WS_i$ , and thus by the estimate of the standard error  $s_i$  for a measurement of unit internal weight.

Table 8 presents the fit of the model to the Gibbs energy measurements in the order of increasing standard error estimates, denoted  $s(\ )$ , and defined in Eq. (49). The third and fourth columns list the set bias  $\bar{\delta}(\ )$  and the mean internal weight  $\bar{w}_i$ , defined in Eqs. (54) and (55), respectively. The fifth column gives the sum of partial leverages<sup>128</sup> of the set.

TABLE 8. Fit of Gibbs energy measurements by regression model

Data set	$s(\ )$ /0.001	$\bar{\delta}(\ )$ /0.001	$\bar{w}_i$	Partial leverage sum	Method

The final column indicates the method of measurement and is included to permit ready comparison of the error estimates and biases of the various experimental techniques. In Table 8, the osmotic coefficients derived from the boiling points of set  $S + H^{27}$  give  $s(\phi) = 0.0031$  and  $\bar{\delta}(\phi) = 0.0006$ ; the cell measurements of set  $B + M^{62}$  completely reevaluated in this work, give  $s(\ln \gamma) = 0.00049$  and  $\bar{\delta}(\ln \gamma) = 0.00007$ ; and the solubilities of set  $K, O + V^{71}$  give  $s(\ln m_s) = 0.00112$  and  $\bar{\delta}(\ln m_s) = -0.00070$ .

The top ten data sets in Table 8 involve seven different experimental techniques which give measurements of high accuracy, with standard errors of the order of or less than 0.0010 on  $\phi$ ,  $\ln \gamma$ , or  $\ln m_s$ . We confirm the high accuracy of the osmotic coefficients of set  $G^{48}$  derived isopiastically from potassium chloride solutions and measurements<sup>120</sup> of concentration cells with transport. After complete reevaluation of sets  $B + M^{62}$  and  $J + G^{63}$  we reconfirm the well-known<sup>1-3</sup> high accuracy of the activity coefficient ratios of these sets derived from measurements of concentration cells with transport. Excellent confirmatory agreement is shown by the activity coefficients of set  $H(DFN)^{54}$  derived from nonequilibrium diffusion measurements. Good agreement is also shown by the activity coefficient measurements of set  $T^{67}$  using glass electrodes in concentration cells without transport. The very accurate boiling point measurements of set  $S^{26}$  define our model at low molality between 60 and 100 °C, and are in excellent agreement with the various cell measurements. The model reaffirms the high accuracy of the freezing points of set  $S + P^{19}$  already well known,<sup>1-3</sup> and the confirmatory good agreement provided by the later measurements (sets  $M, D, G + C^{21}$ ,  $C + VH^{23}$  and  $G + G^{22}$ ) attest to their reliability. Below 1.0m the freezing point measurements are in excellent mutual agreement and with the regression model reflecting the cell measurements at 25 °C and the boiling points up to 100 °C.

The osmotic coefficients derived from the best vapor pressure measurements (sets  $ST^{35}$ ,  $G + A, S + G^{33,51}$ ,  $P + D^{43}$ ,  $A, T + S^{45}$ ,  $N + N^{29,30}$ ,  $G, S, R + C^{44}$ ,  $PT^{40}$ ,  $O + G^{34}$ ,  $L + L^{41,42}$  and  $S, C + G^{37}$ ) show standard errors between 0.0023 and 0.0050 at mean molalities greater than 1.0m. The sets  $P + D$ ,  $A, T + S$ ,  $N + N$ ,  $G, S, R + C$ , and  $O + G$  of static vapor pressure measurements show systematic negative biases between -0.0019 and -0.0041. The residuals of sets  $N + N$ ,  $G, S, R + C$  and  $O + G$  tend to be negative and larger at low molality and low temperature and, conversely, positive and smaller at high molality and high temperature, indicating less than perfect degassing of the salt solutions of these static vapor pressure measurements.

Similar large and systematic negative biases are shown by sets  $R(L, F + S)$  and  $R(G + F)$ , containing Robinson's isopiestic comparisons<sup>1</sup> with static vapor pressure measurements of aqueous potassium chloride<sup>49</sup> and sulphuric acid,<sup>50</sup> respectively. On the contrary, sets  $ST$ ,  $G + A, S + G$ ,  $PT$  and  $R(S + G)$ ,<sup>1</sup> using other similar reliable techniques, do not show any systematic negative biases. We are therefore forced to conclude that the very careful and precise vapor pressure measurements of the Frazer school in sets  $N + N$ ,  $R(L, F + S)$ , and  $R(G + F)$  suffered from failure to remove

substantially all dissolved air from the apparatus. This difficulty of adequate degassing was well recognized by the authors<sup>29,30,33,34,43,44,49-51</sup> for sets  $N + N$ ,  $R(L, F + S)$ ,  $R(G + F)$ ,  $G + A, S + G$ ,  $R(S + G)$ ,  $O + G$ ,  $P + D$ , and  $G, S, R + C$ .

It is found that the negative biases exhibited by the sets of static vapor pressure measurements are sensibly independent of the regression model with up to 43 parameters, but depend mainly on the other data sets present, the negative biases being opposed by the positive biases (i) of the freezing point measurements of sets  $S + P^{19}$ ,  $M, D, G + C^{21}$  and  $G + G^{22}$  (ii) of the cell emf measurements of sets  $H^{60}$  and  $H + N^{61}$  and (iii) of the high-temperature vapor pressure measurements of set  $L + L^{41,42}$ .

The calorimetric data linking the various Gibbs energy data sets are so well determined that we are forced to conclude that either (i) the cell emf measurements from 0 to 50 °C, the diffusion measurements at 25 °C, the boiling point measurements from 60 to 100 °C, the freezing point measurements below 0 °C, the solubility measurements from 0 to 150 °C, and the calorimetric measurements are all simultaneously in excellent mutual agreement, but are all similarly biased and are wrong, or (ii) the osmotic coefficients derived from some of the static vapor pressure measurements at the lower temperatures 20 and 25 °C are biased and systematically low because of less than perfect degassing. Only conclusion (ii) is tenable, more particularly since the sets  $ST$ ,  $G + A, S + G$ ,  $PT$ , and  $R(S + G)$  show no significant bias.

The isopiestic method, properly conducted,<sup>1,3,35,46,48,55,56</sup> is well known as a precise and reliable method for comparison of water activities of solutions down to 0.03m at 25 °C and at temperatures down to 15 and 0 °C. However, the results in Table 8 clearly illustrate the truism that the accuracy of isopiestic measurements is only as good as that of the primary standards used for calibration.

Greatest precision, rather than accuracy, is shown by the isopiestic osmotic coefficients of set  $G^{48}$  which confirm that our model for aqueous sodium chloride between 0.03 and 0.1m is in precise agreement with the very accurate cell measurements<sup>120</sup> of aqueous potassium chloride. Similar less accurate osmotic coefficients between 0.1 and 1.0m are provided by set  $R(H)$ , which depends on the less accurate measurements<sup>53,54,60,61</sup> of cells without transport. Stokes<sup>35</sup> used a painstaking bithermal-isopiestic technique with a pure water standard to obtain the most accurate set,  $ST$ , of solution vapor pressure measurements between 4.0 and 5.9m. In set  $R + S^{46}$  changes of sodium chloride activity coefficient are determined by integration of isopiestic data between 0.1 and 4.0m. The osmotic coefficients of set  $R(H + C)$ , derived from the integration of cell measurements,<sup>1,53</sup> are found to be uniformly low and biased by -0.0030 at all molalities from 1.4 to 3.6m. The isopiestic data sets  $G$ ,  $R(H)$ ,  $ST$ , and  $R + S$  having the best accuracy exhibit no significant bias.

Platford *et al.*<sup>55-57</sup> used aqueous urea and sulphuric acid as isopiestic standards to determine the osmotic coefficients of sodium chloride solutions with an assessed accuracy of  $\pm 0.003$  and  $\pm 0.004$  at 15 and 0 °C, respectively. Those studies,<sup>56,57</sup> together with the work of Stokes,<sup>58,59</sup> show that the osmotic coefficients of the sulphuric acid and

of the urea standards at 0 °C are not unambiguously well defined, but are systematically lower by -0.002 to -0.005 on  $\phi$  for sodium chloride when extrapolated from the osmotic coefficients<sup>3,59</sup> at 25 °C using thermal data<sup>56</sup> than when evaluated with small corrections from the freezing point measurements.<sup>19,58</sup> Since the freezing point measurements were accurate to  $\pm 0.001^{\circ}\text{C}$  or better<sup>19</sup> on the osmotic coefficient at the freezing temperature, this strongly indicates that the osmotic coefficients at 25 °C of the sulphuric acid<sup>3</sup> and aqueous urea<sup>59</sup> standards used for calibration are systematically too low. Our regression model reconfirms these systematic negative biases quantitatively at 15 and 0 °C. The sodium chloride osmotic coefficients of set C + P<sup>55</sup> at 15 °C are found to be uniformly low and biased by -0.0039 between 1.0 and 4.0m. The sodium chloride osmotic coefficients of set P<sup>56</sup> at 0 °C are in good agreement with our model between 0.4 and 2.1m, but are seriously low and show large negative residuals between 2.7 and 6.1m.

The sodium chloride osmotic coefficients and isopiestic comparisons of set S, H + W<sup>47</sup> are based on freezing points<sup>19</sup> at low molality and on static<sup>29,30</sup> and dynamic<sup>32</sup> vapor pressures at high molality. The smoothed osmotic coefficients of set S, H + W are in good agreement with our model up to 1.2m, show a systematic negative deviation of -0.0080 at 2.0m, agree well at 4.0m, and show a large positive deviation of 0.0172 at 6.0m. Osmotic coefficients of set P + N,<sup>32</sup> based on the dynamic vapor pressure measurements of Fordemwalt, exhibit large residuals which fluctuate from -0.0156 at 0.4m, to -0.0077 at 2.0m, through zero near 4.0m, and increase to 0.0162 at 6.0m. It is apparent that the deviations of set S, H + W above 2.0m are highly correlated with those of set P + N used for calibration.

The large standard error and almost constant negative bias of all osmotic coefficients of set R<sup>18</sup> show that these precisely determined freezing point depressions are consistently too small by about 1%, possibly due to faulty thermocouple calibration. This is particularly unfortunate since there are no accurate freezing point measurements for aqueous sodium chloride above 3.6m and below -13.6 °C.

Results in Table 8 shows that the activity coefficients of sodium chloride (i) are determined most accurately in sets B + M<sup>62</sup> and J + G<sup>63</sup> by measurements of concentration cells with transference, (ii) are less accurately determined in sets T,<sup>67</sup> C,<sup>65</sup> H,<sup>60</sup> and H + N,<sup>61</sup> by measurements of concentration cells without transference, and (iii) are least accurately determined in sets M + P<sup>68</sup> and L + A<sup>66</sup> by measurements of single compartment cells. These cell measurements, apart from the oldest and small set H, exhibit relatively small biases.

The regression model accurately fits the activity measurements of the large data sets H + N and C at all temperatures and compositions, while the residuals of  $\ln \gamma$  provide no evidence of anomalous behavior by silver/silver chloride electrodes in the more concentrated sodium chloride solutions (above 2.5m<sup>1</sup> and above 2.0m<sup>7</sup>).

The excellent fit of the regression model to the solubilities of the composite data set S + L, ICT at all temperatures from 0 to 150 °C strongly supports the data evaluation of the authors.<sup>42,69,70</sup> Within the set, the older evaluated data between 0 and 55 °C from International Critical Tables<sup>69</sup> exhibit a standard error of 0.0019. The fit of the modern measurements of set K, O + V<sup>71</sup> between 0 and 45 °C is good and provides independent confirmation of the values of Linke.<sup>70</sup> The set P + C<sup>72</sup> exhibits a large standard error; all solubilities are low and give negative residuals which become progressively larger below 40 °C.

Table 9 presents results of the fit of the regression model to the sets of heat of dilution measurements, listed in order of their standard error estimates  $s(\Delta H_d/R)$ . The third to fifth columns show the set bias  $\bar{s}(\Delta H_d/R)$ , the mean internal weight  $\bar{w}_i$ , and the sum of the partial leverages. The final column indicates the experimental method employed, denoted CAL for batch-calorimeter and FCAL for flow-calorimeter measurements.

The data sets V,<sup>78</sup> Y + M,<sup>76</sup> and Y + V,<sup>74</sup> using the Young type of calorimeter, show high accuracies at 25 °C. In set Y + V, the two atypical measurements using large dilutions show an increased standard error of 1.1 K. The mea-

TABLE 9. Fit of heat of dilution measurements by regression model

surements of set Y + M show increased standard errors of 0.076 and 0.32 K at the lower temperatures 12.6 and 0.2 °C, respectively. The regression model is in good agreement with the flow-calorimeter measurements of sets F, L, P + D<sup>121</sup> and F, L + D(D).<sup>105</sup> The model also shows good agreement and no significant bias from set B, M + C.<sup>122</sup> The batch-calorimeter measurements of set L + M<sup>81</sup> at 30 °C exhibit uniformly negative residuals which are about one-half as large as those of the earlier set M, H + H<sup>80</sup> at 25 °C.

The flow-calorimeter measurements of set M + W<sup>83</sup> give weighted residuals which still increase slightly and systematically with increase of molality above 1.3m, despite all efforts to apply rational internal weights. The normalized residuals show just less than one standard error of negative bias at 25 °C, essentially no bias at 50 and 75 °C, and about one standard error of positive bias at 100 °C. The authors of set M + W consider the measurements at 100 °C to be less reliable,<sup>84</sup> and this is confirmed by the corresponding residuals which indicate an increased standard error of 1.4 K at 100 °C. The measurements of set MR + W<sup>84</sup> essentially define our regression model at 75, 100, and 150 °C, and the fit to these data is excellent with no bias at each temperature. The standard error of 0.51 K of set MR + W refers to a measurement comprised of a single run; for a measurement comprised of  $r$  replicate runs, the standard error is divided by the square root of  $r$ . The extensive batch-calorimeter measurements of set E + A<sup>79</sup> are unbiased at each temperature but show increasing standard errors of 1.8, 1.8, 2.7, and 6.1 K at the higher temperatures 50, 60, 70, and 80 °C, respectively. Further comparison of the regression model with sets E + A, M + W, and MR + W is deferred until later discussion of other models and tabulations.

Table 10 shows the fit of the regression model to the sets of heat of solution measurements, listed in the order of their increasing standard error estimates  $s(\Delta H_s/R)$ . The third to fifth columns show the set bias  $\bar{\delta}(\Delta H_s/R)$ , the mean internal weight  $\bar{w}_i$ , and the sum of the partial leverages. The final column indicates the batch-calorimetric method employed, denoted CAL for dissolution of solid sodium chloride in water and CALAQ for dissolution in aqueous sodium chloride solution.

The standard errors of heat of solution measurements are about one order of magnitude larger than those of heat of dilution measurements. The weighted mean value of the thirteen data sets in Table 10 defines the heat of solution parameter of the model,  $(\Delta H_s)_{\theta}/R$  at 25 °C.

The data sets L, J + M<sup>88,89</sup> and W + L<sup>86,87</sup> were corrected as indicated by Benson and Benson.<sup>90</sup> The measurement of set L, J + M at 25 °C exhibit a remarkably small standard error, the measurements at 20 °C are slightly less accurate with a standard error of 0.93 K. The regression model fitted set B<sup>93</sup> within experimental error below 0.2m, but indicates a small positive bias of the measurements at higher molality. The model fits set D + B<sup>94</sup> well within experimental error, but the fit of the earlier set B + B<sup>90</sup> is not as good and indicates a positive bias of the measurements above 0.2m.

For set C + VH(IH)<sup>82</sup> we used the authors' relative errors for the measurements at 10 and 5 °C and the model indicates the increased standard errors of 10 and 17 K, respectively, as the temperature decreased. The differential heat of solution measurements of set C + VH(DH)<sup>82</sup> show predominantly negative residuals, which tend to be larger at higher molality and at low temperature.

The measurements of set TO + L<sup>96</sup> yield residuals which are nonrandom and are systematically correlated with molality at all temperatures in a manner that indicates isothermal data smoothing. The low-temperature measurements of set TO + L at 5 and 10 °C indicate increased standard error estimates of 24 K. All error estimates for set TO + L are probably too small.

For set C + C,<sup>92</sup> the standard error refers to a measurement comprised of a single run; for measurements comprised of  $r$  runs the standard error is divided by the square root of  $r$ . The measurements of set C + C exhibit mainly negative residuals which increase systematically from less than - 3 K at 55 °C and less than - 4 K at 45 °C to usually less than - 10 K at 35 and 25 °C, to usually less than - 15 K at 20 and 15 °C, to about - 20 K at 10 °C, and to less than - 40 K near 0 °C. Above 55 °C the residuals are all negative and again increase systematically from about - 16 K at 65 °C to about - 40 K at 95 °C. The measurements of set

TABLE 11. Fit of apparent heat capacity measurements by regression model

Data set	$s(C_{p,\phi}/R)$	$\bar{s}(C_{p,\phi}/R)$	$\bar{w}$	Partial leverage sum	Method
D, DV, P + P	0.036	-0.012	0.65	0.64	FCAL
T + L	0.037	0.004	0.54	3.94	CAL
O	0.054	-0.038	0.71	0.25	CAL
S, W, M + H	0.056	-0.038	0.75	0.24	FCAL
A + W	0.072	0.027	0.59	2.13	FCAL
P, L, P + D	0.081	-0.045	0.65	0.11	FCAL
R + R	0.097	-0.009	0.74	0.088	CAL
F, L + D	0.098	-0.004	0.72	0.13	FCAL
E + S	0.14	0.02	1.0	0.024	CAL
P, F + D	0.16	0.01	0.54	0.42	FCAL
CR	0.40	0.24	1.0	0.002	CAL
L + B	0.41	-0.24	0.65	0.49	CAL
HS	0.61	0.69	0.22	0.002	CAL
P, S + F	0.64	0.12	1.0	0.38	CAL
H + G	0.71	0.04	0.75	0.009	CAL
W	0.84	0.68	0.61	0.004	CAL

G, M + C<sup>95</sup> show mean biases of about -0.7 and +0.7 standard errors at 114 and 150 °C, respectively.

Table 11 shows the fit of the regression model to the sets of heat capacity measurements, listed in order of their increasing standard error estimates of apparent molal heat capacity,  $s(C_{p,\phi}/R)$ . The third to fifth columns show the set bias  $\bar{s}(C_{p,\phi}/R)$ , the mean internal weight  $\bar{w}$ , and the sum of the partial leverages. The final column indicates the experimental method used, denoted CAL for batch-calorimeter and FCAL for flow-calorimeter.

The regression model at lower temperatures is essentially defined by the first eight sets in Table 11. At low molalities the model follows the very precise flow-calorimeter measurements of sets D, DV, P + P,<sup>110</sup> S, W, M + H,<sup>109</sup> A + W,<sup>125</sup> P, L, P + D,<sup>103</sup> and F, L + D<sup>105</sup>; at high molalities it follows the accurate batch-calorimeter measurements of sets T + L,<sup>112</sup> O,<sup>113</sup> and R + R.<sup>98</sup> The model accurately fits the extensive measurements of set T + L at all compositions and all temperatures from 5 to 85 °C, and shows an increased standard error of 0.11 for the measurements at 5 °C. At higher temperatures, the model follows the measurements of sets L + B<sup>104</sup> and P, S + F,<sup>108</sup> but it is mainly defined at higher concentrations by the heat of dilution measurements of sets M + W<sup>83</sup> and MR + W.<sup>84</sup>

Considerable effort was spent attempting to fit the measurements of set P, F + D<sup>106</sup> with about the same range of standard error as that shown by sets D, DV, P + P, P, L, P + D, and F, L + D at 25 °C. None of our regression models was able to fit the measurements of set P, F + D with comparable small error estimates. For measurements between 15 and 45 °C, the standard error is 0.16; for those at the lower temperatures 5 and 1.5 °C, the standard error is increased to 0.76. The residuals at 1.5, 5, and 15 °C are mainly negative and show a negative bias of about one standard error. The residuals at 35 °C are mainly positive with a bias of about one standard error, and those at 45 °C are mainly positive with a bias of about one-half of a standard error.

#### 4. Comparison of Earlier Tabulations with the Regression Model

##### 4.1. Development of the Regression Model

In the development of our regression model for aqueous sodium chloride we were concerned initially with the ability of an extended Pitzer-type<sup>8</sup> equation, with fourth and fifth virial parameters  $D_0$  and  $E_0$ , to provide a proper fit of precise osmotic coefficients over the whole composition range. In the earlier and extensive testing of representative equations for various aqueous electrolytes at 25 °C, Pitzer<sup>8,9</sup> had shown that his three-parameter equation fitted the critically evaluated sodium chloride osmotic coefficients of Robinson<sup>1</sup> with a root-mean-squared deviation of 0.0007 over the range of 0.1 to 6.0m NaCl. We find that the Pitzer-type equations with three parameters ( $Q_0, B_0, C_0$ ), four parameters ( $Q_0, B_0, C_0, D_0$ ), and five parameters ( $Q_0, B_0, C_0, D_0, E_0$ ) fit the osmotic coefficients (i) of Robinson<sup>1,3</sup> with root-mean-squared deviations of 0.00073, 0.00029, and 0.00026, respectively, and (ii) of Hamer and Wu<sup>6</sup> with root-mean-squared deviations of 0.00071, 0.00028, and 0.00027, respectively.

The five-parameter Pitzer-type equations equally over-fit the osmotic coefficients both of Robinson and of Hamer and Wu. Clearly the three-parameter Pitzer equations underfit and provide almost equally poorer fits of both sets<sup>1,6</sup> of osmotic coefficients. The four-parameter Pitzer-type equations properly fit, almost equally well, both the osmotic coefficients evaluated by Robinson and those calculated by Hamer and Wu. We find that the four-parameter Pitzer-type equation fits the osmotic coefficients of Robinson<sup>1</sup> slightly better than the nonlinear four-parameter equation of Hamer and Wu<sup>6</sup> which exhibits a root-mean-squared deviation of 0.00044. Comparison of residuals confirms that the linear four-parameter Pitzer-type equation represents the osmotic coefficients of Robinson as validly as the earlier nonlinear type of equation.<sup>6,11</sup>

During the later development of our regression model, the inclusion of numerous accurate calorimetric enthalpy measurements forced us to include the virial parameters  $D_1$  and  $E_1$  and the higher order parameters up to  $D_4$  and  $E_2$ , while the low-temperature solubility and freezing point measurements showed the need to include the parameter  $D_0$  and  $E_0$ . In our final model, the statistical  $t$  values for  $D_0$  and  $E_0$  at 0 °C are 8.6 and 5.2, respectively, showing that these parameters are highly significant and essential for the proper fit of the model to the Gibbs energy measurements at low temperatures.

#### 4.2. Osmotic and Activity Coefficient Data

The deviations from our regression model  $\delta\phi = (\phi_{\text{author}} - \phi_{\text{model}})$  of the tabulated osmotic coefficients at 25 °C of the authors Robinson,<sup>1</sup> Hamer and Wu,<sup>6</sup> and Gibbard *et al.*<sup>7</sup> are shown in Fig. 2, plotted for clarity against the logarithm of molality. Deviations exhibited by the data points of Robinson and by the curve of Hamer and Wu are closely similar because Hamer and Wu<sup>6</sup> fitted the tabulated values of Robinson<sup>1</sup> provided by Robinson and Stokes.<sup>3</sup> At molalities below 1.0m and above 4.0m, the osmotic coefficients of Robinson and of Hamer and Wu deviate by less than  $\pm 0.0020$  from our model and may be considered in rough agreement with it. Between 1.2 and 3.8m Robinson's osmotic coefficients exhibit negative deviations greater than  $-0.0020$ , with maximum deviation  $-0.0036$  at 1.4m.

The relative deviations  $\delta\phi/\sigma\phi$  of the osmotic coefficients, relative to their standard error estimates  $\sigma\phi$ , are shown for the same data in Fig. 3. We define relative deviations of magnitude less than ten standard errors as being within the region of possible agreement with our regression model, and those greater than ten standard errors being defined as in the region of significant deviation and of definite disagreement. Reference to Fig. 3 shows that the osmotic coefficients of Robinson and of Hamer and Wu are in possible agreement with our model between 0.1 and 0.3m and between 4.0 and 6.0m, but are in definite disagreement with

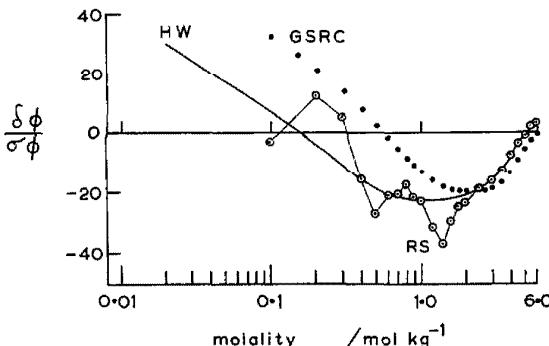

FIG. 3. Relative deviations  $\delta\phi/\sigma\phi$  of the osmotic coefficient tabulations from our model divided by the standard error at 25 °C; relative deviations (i) of Robinson (Refs. 1 and 3) are shown by the open circles denoted RS, (ii) of Hamer and Wu (Ref. 6) by the solid curve denoted HW, and (iii) of Gibbard *et al.* (Ref. 7) by the filled circles denoted GSRC.

large negative relative deviations between  $-10$  and  $-36$  standard errors at molalities between  $0.4$  and  $3.6m$ . These negative deviations are so highly significant that we are forced to conclude that the tabulated osmotic coefficients of Robinson<sup>1,3</sup> are too low by  $-0.0021$  to  $-0.0036$  between  $1.2$  and  $3.8m$ . Osmotic coefficients from the equation of Hamer and Wu<sup>6</sup> are similarly too small by  $-0.0032$  at  $2.5$  and  $3.0m$ .

The corresponding absolute and relative deviations ( $\delta\gamma$  and  $\delta\gamma/\sigma\gamma$ ) of the tabulated activity coefficients<sup>1,6,7</sup> at 25 °C are shown in Figs. 4 and 5, respectively. Below  $1.2m$ , Robinson's activity coefficients<sup>1,3</sup> deviate from our model by less than  $\pm 0.0020$ , above  $1.2m$  the deviations are all negative and greater than  $-0.0020$ , with maximum deviation  $-0.0052$  at  $3.4m$ . The relative deviations in Fig. 5 show that Robinson's activity coefficients are high between  $0.1$  and  $0.3m$  and are significantly too low between  $1.0$  and  $4.6m$ . The negative deviations are so significant that we have to conclude that the activity coefficients of Robinson<sup>1,3</sup> are too small by  $-0.0022$  to  $-0.0052$  between  $1.2$  and  $4.6m$ .

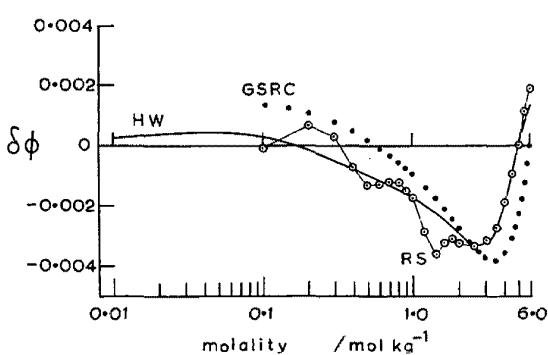

FIG. 2. Deviations  $\delta\phi$  of osmotic coefficient tabulations (Refs. 1, 3, 6, and 7) from our regression model at 25 °C; deviations (i) of Robinson (Refs. 1 and 3) are shown by the curves denoted RS, (ii) of Hamer and Wu (Ref. 6) by the solid curve denoted HW, and (iii) of Gibbard *et al.* (Ref. 7) by the filled circles denoted GSRC.

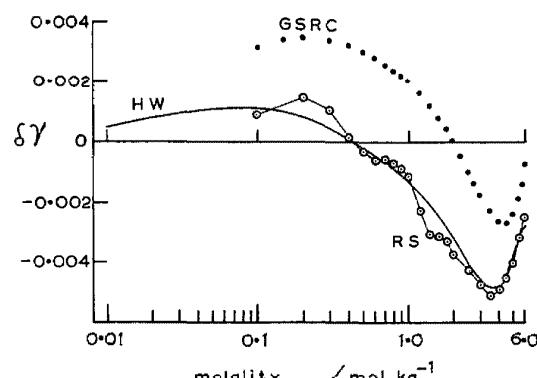

FIG. 4. Deviations  $\delta\gamma$  of activity coefficient tabulations from our regression model at 25 °C; deviations (i) of Robinson (Refs. 1 and 3) are shown by the open circles denoted RS, (ii) of Hamer and Wu (Ref. 6) by the solid curve denoted HW, and (iii) of Gibbard *et al.* (Ref. 7) by the filled circles denoted GSRC.

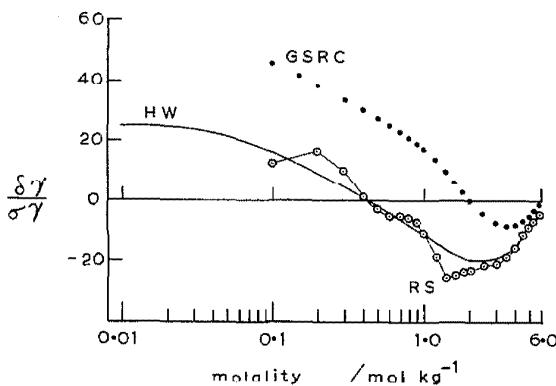

FIG. 5. Relative deviations  $\delta\gamma/\sigma\gamma$  of the activity coefficient tabulations from our model divided by the standard error at 25 °C: relative deviations (i) of Robinson [Refs. 1 and 3] are shown by the open circles denoted RS, (ii) of Hamer and Wu [Ref. 6] by the solid curve denoted HW, and (iii) of Gibbard *et al.* [Ref. 7] by the filled circles denoted GSRC.

Activity coefficients from the equation of Hamer and Wu<sup>6</sup> are correspondingly too small by  $-0.0048$  and  $-0.0047$  at  $3.5$  and  $4.0m$ , respectively.

Shown in Fig. 2, the osmotic coefficients of Gibbard *et al.*<sup>7</sup> at 25 °C exhibit significant positive deviations from our model between  $0.1$  and  $0.3m$ , and significant negative deviations between  $0.9$  and  $4.0m$ , with maximum deviation of  $-0.0039$  at  $3.5m$ . The corresponding activity coefficients, shown in Fig. 4, give large significant positive deviations between  $0.1$  and  $1.2m$ , with maximum deviation  $0.0035$  at  $0.2m$ , and negative deviations above  $2.0m$ , with maximum negative deviation  $-0.0028$  at  $4.5m$ . The relative deviations, shown in Figs. 3 and 5, vary sharply from  $+32$  to  $-20$  standard errors between  $0.1$  and  $2.0m$  for the osmotic coefficient, and from  $+45$  to  $-9$  standard errors between  $0.1$  and  $4.0m$  for the activity coefficient. These results force us to conclude that (i) the osmotic coefficients of Gibbard *et al.*<sup>7</sup> at 25 °C are too large by about  $0.0010$  between  $0.1$  and  $0.3m$  and are too small by up to  $-0.0039$  between  $0.9$  and  $4.5m$  and (ii) their activity coefficients<sup>7</sup> at 25 °C are too large

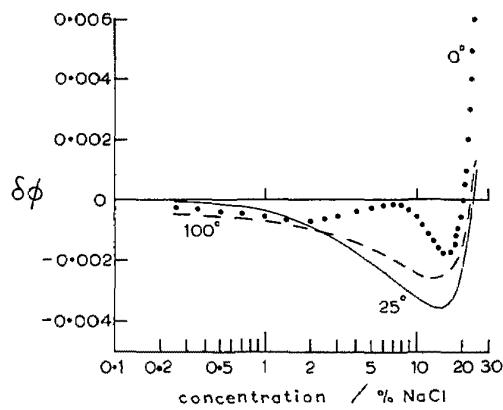

FIG. 6. Deviations  $\delta\phi$  of the osmotic coefficients of Pitzer *et al.* (Ref. 12) from our regression model at 0, 25, and 100 °C.

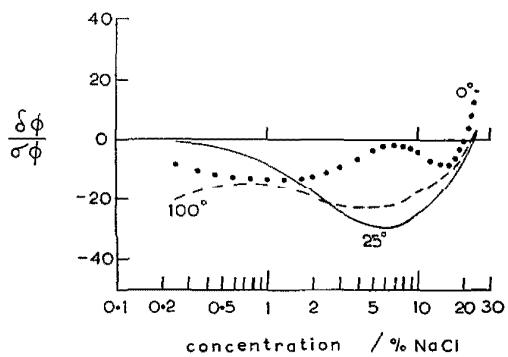

FIG. 7. Relative deviations  $\delta\phi/\sigma\phi$  of the osmotic coefficients of Pitzer *et al.* (Ref. 12) from our model divided by the standard error at 0, 25, and 100 °C.

by up to  $0.0035$  between  $0.1$  and  $1.4m$  and are in possible agreement with our model above  $1.6m$ .

The absolute and relative deviations of the osmotic coefficients of Pitzer *et al.*<sup>12</sup> at 0, 25, and 100 °C are shown in Figs. 6 and 7. The deviations are mainly and significantly negative over most of the composition and temperature range, become small and positive above  $5.1m$  (23%) at 25 and 100 °C, and are positive and significant only above  $5.1m$  at 0 °C. At 25 °C the negative deviations are greater than  $-0.0020$  between  $0.9$  and  $4.5m$  (5% and 21%) and exhibit a maximum of  $-0.0036$  at  $2.8m$  (14%). Corresponding relative deviations are greater than  $-10$  standard errors between  $0.3$  and  $4.0m$  (1.5% and 19%) with a maximum of  $-29$  standard errors at  $1.3m$  (7% NaCl).

The deviations at 25 °C are closely similar to those of Robinson<sup>1</sup> and of Hamer and Wu<sup>6</sup> shown in Figs. 2 and 3. The similarity probably arises from their common data base<sup>1</sup> because Pitzer *et al.* at low temperature used the vapor pressures<sup>34</sup> used by Robinson and the isopiestic measurements<sup>55,56</sup> directly traceable to Robinson.

The deviation curves at intermediate temperatures between 25 and 100 °C are quantitatively similar to those shown and indicate that the temperature dependence of the osmotic coefficients of Pitzer *et al.*<sup>12</sup> is in approximate agreement with our model between 25 and 100 °C. The deviation curves at 0 °C are atypical of those between 25 and 100 °C and demonstrate more substantial differences between the temperature coefficients of Pitzer *et al.* and those from our model at lower temperatures between 25 and 0 °C.

Most recently, after this work had been submitted for publication, Pitzer, Peiper, and Busey<sup>136</sup> have given a new model for NaCl(aq) by fitting the evaluated osmotic coefficients of Robinson<sup>1,3</sup> at 25 °C, the evaluated heats of dilution of Parker,<sup>4</sup> together with the measurements of other authors. The new osmotic coefficient values of Pitzer *et al.*<sup>136</sup> deviate from our regression model at 25, 50, and 100 °C in a manner similar to their earlier work,<sup>12</sup> shown in Figs. 6 and 7, with similar negative deviations at 25 °C of  $-0.0035$  and  $-0.0037$  ( $-17$  and  $-14$  standard errors) at  $3.0$  and  $4.0m$ , respectively. These significant negative deviations<sup>136</sup> at 25 °C directly reflect the deviations of the original Robinson evaluation.<sup>1,3</sup> At 0 °C, the new osmotic coefficient values of

Pitzer *et al.*<sup>136</sup> deviate more significantly from our regression model than their earlier work<sup>12</sup> and than the new values<sup>136</sup> at 25 °C. At 0 °C, these osmotic coefficient deviations are -0.0055 and +0.0121 (-28 and +24 standard errors) at 3.0 and 6.0 m, respectively. The osmotic coefficient value<sup>136</sup> at 3.0 m is in significant disagreement with freezing point measurements,<sup>19-23</sup> the value<sup>136</sup> at 6.0 m through the Gibbs-Duhem is in significant indirect disagreement with solubility data.<sup>69-71</sup> In addition, at 0 °C, the activity coefficient value of Pitzer *et al.*<sup>136</sup> [from their Eq. (9)] for saturated NaCl(aq) deviates from our regression model by 0.0101 (17 standard errors), in significant disagreement with solubility data.<sup>69-71</sup> Pitzer, Peiper, and Busey have discussed the lack of fit of their model with solubility data at 0 °C and the model's inability to fit various very rapidly varying NaCl(aq) properties near 0 °C.

We have made extensive computational investigations into the reason why our regression model always shows conclusively that the tabulated osmotic coefficients<sup>1,3,6,7,12,136</sup> at 25 °C are systematically low by more than -0.0020 between 1.2 and 3.8 m, and are significantly low by more than -10 standard errors between 0.4 and 3.6 m. The reason for this discrepancy is that no earlier analysis has correctly included (weighted) the measurements of the freezing<sup>18-24</sup> and boiling<sup>26-28,123,124</sup> points relative to those of the vapor pressures<sup>29-45</sup> and electrochemical cells.<sup>60-68</sup>

The data available to Robinson<sup>1</sup> were insufficiently complete. Hamer and Wu<sup>6</sup> indicated they fitted the tables of Robinson and Stokes.<sup>1,3</sup> The model of Gibbard *et al.*<sup>7</sup> included all osmotic coefficients at unit weight and thus greatly underestimated the effect of the more accurate freezing point<sup>19,21,22</sup> and boiling point<sup>26,27</sup> measurements. The model of Pitzer *et al.*<sup>12</sup> included no freezing point measurements and was based on the low-temperature osmotic coefficients of Platford,<sup>56</sup> Childs and Platford,<sup>55</sup> Olynyk and Gordon,<sup>34</sup> and of Gibbard *et al.*,<sup>7</sup> which data sets, respectively, exhibit negative biases relative to our model of -0.0041, -0.0039, -0.0041, and -0.0049 (data<sup>7</sup> at 25 °C). The most recent model by Pitzer, Peiper, and Busey<sup>136</sup> was heavily based on the evaluated osmotic coefficients of Robinson and Stokes.<sup>1,3</sup>

These findings of our model agree well with the original alternative suggestion of Robinson<sup>1</sup> that the cell measurements of Harned *et al.*<sup>53,54,60,61</sup> were substantially correct at higher molalities and that Robinson's osmotic coefficients were too low, not as suggested<sup>1</sup> by -0.0060 above 2.5 m, but by -0.0036 between 1.0 and 4.0 m.

After completion of our regression analysis, with its compelling demonstration that earlier osmotic coefficients at 25 °C were significantly too small, we wished to further reconfirm our findings and experimentally demonstrate the effect of the freezing and boiling point data on the regression model. In these tests we evaluated the weighted least-squares regression models for abridged input data sets which included all other measurements but excluded (i) the 147 freezing point measurements,<sup>18-24</sup> (ii) the 158 boiling point measurements,<sup>26-28,123,124</sup> and (iii) both (i) and (ii). The osmotic coefficients at 25 °C evaluated from these abridged models each exhibited similar negative deviations relative to our final model with all 2428 input data included. Smallest negative

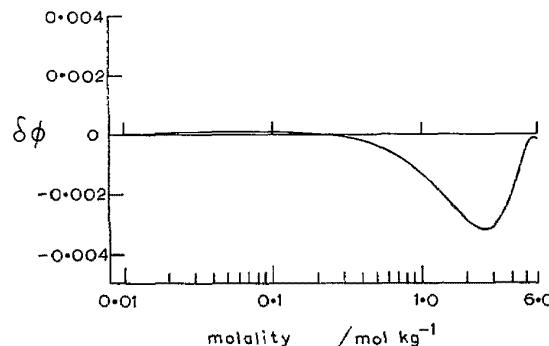

FIG. 8. The deviation  $\delta\phi$  of osmotic coefficients at 25 °C for the regression model of an abridged data set, excluding freezing and boiling point measurements, relative to our final model of the complete data set.

deviations resulted from (ii) exclusion of the boiling points only; larger negative deviations resulted from (i) exclusion of the freezing points only; and the largest negative deviations (shown in Fig. 8) resulted from (iii) exclusion of both the freezing and the boiling points. The remarkable similarity in respect to shape, position, and magnitude of the deviation curves in Fig. 8 with the comparable curve in Figs. 2 and 6 illustrates quantitatively and confirms our contention that earlier data analyses<sup>1,3,6-12,136</sup> have not adequately weighted the freezing and boiling point data.

#### 4.3. Apparent Molal Relative Enthalpy and Heat of Dilution Data

By fortunate hap, one of our earlier and less complete regression models proved that an extended Pitzer-type model with five enthalpy parameters ( $Q_1, B_1, C_1, D_1, E_1$ ) could accurately mimic precise values of  $L_\phi$  over the whole composition range. For all compositions at 25 °C that model gave values of  $L_\phi$  and  $L_2$  which were in remarkable but coincidental agreement with all of those values critically evaluated by Parker.<sup>4</sup> The  $L_\phi$  values of Parker gave deviations from the model which showed seven changes of sign, with mean deviation 2.1 J mol<sup>-1</sup> and root-mean-squared deviation 3.7 J mol<sup>-1</sup>; the  $L_2$  values gave deviations which showed ten changes of sign, with mean deviation 2.2 J mol<sup>-1</sup> and root-mean-squared deviation 11 J mol<sup>-1</sup>. This level of agreement is well within the combined limits of error and provides independent support for the essential correctness of the Parker  $L_\phi$  values at 25 °C, since many of the measurements included in and defining that earlier model were unavailable to Parker. Deviations of the Parker  $L_\phi$  values from our final model are slightly larger and negative, and are discussed elsewhere.

We also needed to test the ability of our model, with five enthalpy parameters, to fit isothermal heat of dilution measurements compared with other models using power series in  $m^{1/2}$ .<sup>79,83,84</sup> A good test was provided by the extensive and accurate heat of dilution measurements and equations recently published by Mayrath and Wood.<sup>84</sup> We find that, providing we use the same value for the Debye-Hückel limiting slope as the authors,<sup>84</sup> our Pitzer-type model can accurately fit the  $L_d$  values from their five-parameter equations

TABLE 12. Deviations of  $L_\phi$  tabulations from regression model

60	-19	20				
70	-90	97				
75			-10	16	43	43
80	-64	90				
100			-22	68	35	35
150					-21	22
Full range	-37	63	-1	40	14	30

<sup>a</sup> Reference 79.<sup>b</sup> Reference 83.<sup>c</sup> Reference 84.

between 0.1 and 6.0m with five changes of sign of the deviations and with root-mean-squared deviations of 1.3, 1.8, and 1.0 J mol<sup>-1</sup> at 75, 100, and 150.5 °C, respectively. Since these deviations are small, systematic, and uniform, and are about an order of magnitude smaller than the accuracy of the original equations and their supporting measurements, we find that our Pitzer-type model with five parameters can provide an equally valid alternate fit of these heat of dilution data.<sup>84</sup>

Additional tests confirm that our model can also properly fit all tabulated  $L_\phi$  values of Messikomer and Wood<sup>83</sup> at 25, 50, and 75 °C and of Ensor and Anderson<sup>79</sup> at 40, 50, and 60 °C, respectively, with 11, 7, 13, 11, 5, and 5 changes of sign of the deviations, and with root-mean-squared deviations of 4.1, 4.2, 2.5, 3.4, 4.4, and 3.2 J mol<sup>-1</sup>.

Our final regression model fits the measurements of Mayrath and Wood<sup>84</sup> from 75 to 150.5 °C with a standard error of 4.3 J mol<sup>-1</sup> for a single measurement of unit weight; this error estimate compares favorably with those of 9, 5, and 13 J mol<sup>-1</sup> given by the authors<sup>84</sup> for the standard error of a single point in their fits at 348.15, 373.15, and 423.65 K, respectively. The measurements of Messikomer and Wood<sup>83</sup> are fitted from 25 to 75 °C with a standard error of 5.9 J mol<sup>-1</sup>, and those at 100 °C with an increased standard error of 12 J mol<sup>-1</sup>. The measurements of Ensor and Anderson<sup>79</sup> are fitted at 40, 50, 60, 70, and 80 °C with standard errors of 11, 15, 15, 23, and 51 J mol<sup>-1</sup>, respectively.

We made many analyses of variance comparisons of the deviations between the tabulated  $L_\phi$  values of Ensor and Anderson, of Messikomer and Wood, and of Mayrath and Wood between themselves and of their deviations from our model. The  $L_\phi$  values of our model lie properly between the tabulations,<sup>79,83,84</sup> and exhibit smaller variances from the tabulations than those between the tabulations. In Table 12, we show the mean deviation and root-mean-squared deviation of the tabulated<sup>79,83,84</sup>  $L_\phi$  values from our model at the experimental temperatures from 0.1 to 5.0m<sup>83</sup> and to 6.0m.<sup>79,84</sup> The  $L_\phi$  values of Ensor and Anderson show mainly negative deviations which become larger at 70 and 80 °C.

The  $L_\phi$  values of Messikomer and Wood show large deviations only at 100 °C, where experimental difficulties were experienced.<sup>83,84</sup> The  $L_\phi$  values of Mayrath and Wood show mainly positive deviations, none large. The deviations in Table 12 are not random but systematic and reflect biases due to use of different values for the Debye-Hückel limiting slope, use and extrapolation of different models to infinite dilution, and use of different techniques to measure heats of dilution.

Our final model estimates of  $L_\phi$  and  $L_2$  at 25 °C are in reasonable agreement with those compiled by Parker,<sup>4</sup> recognizing the very different data bases<sup>77-84</sup> and the entirely different methods of evaluation. The 46  $L_\phi$  values of Parker at 25 °C between 0.0001 and 6.0m deviate from our model with three changes of sign, with mean deviation -4.9 J mol<sup>-1</sup>, and root-mean-squared deviation 6.8 J mol<sup>-1</sup>. The deviations shown in Fig. 9 are small below 0.1m, are almost constant about -5 J mol<sup>-1</sup> between 0.1 and 3.0m, and increase from -10 to -15 J mol<sup>-1</sup> between 3.5 and 6.0m. The 38  $L_\phi$  values between 0.018 and 6.0m show uniformly

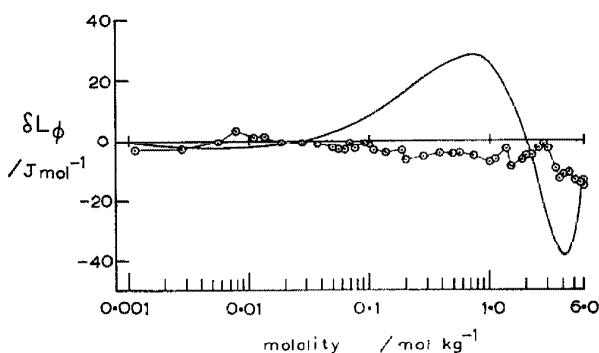

FIG. 9. Deviations  $\delta L_\phi$  of apparent molal relative enthalpy tabulations from the regression model at 25 °C; deviations of Parker (Ref. 4) are shown by the open circles, of Smith, Cone, and Van Hook (Ref. 126) by the solid curve.

negative deviations from our model of about  $-6$  standard errors. The  $29 L_2$  values of Parker at  $25^\circ\text{C}$  between  $0.005$  and  $5.8m$  deviate from our model with eight changes of sign, with mean deviation  $-6.0 \text{ J mol}^{-1}$ , and root-mean-squared deviation  $11 \text{ J mol}^{-1}$ .

The equation proposed by Smith, Cone, and Van Hook<sup>126</sup> gives values of  $L_\phi$  at  $25^\circ\text{C}$  which deviate systematically and significantly from our model with large positive deviations between  $0.028$  and  $2.0m$  and with large negative deviations above  $2.1m$ ; the extremum deviations are  $28 \text{ J mol}^{-1}$  (26 standard errors) at  $0.74m$  and  $-37 \text{ J mol}^{-1}$  ( $-22$  standard errors) at  $4.6m$ . The proposed equation<sup>126</sup> is unreliable since 26 of its estimates of  $L_\phi$  between  $0.005$  and  $5.8m$  exhibit a root-mean-squared deviation from our model of 22 standard errors.

#### 4.4. Heat of Solution Data

Our regression model provides a consensus of all<sup>85-97</sup> calorimetric heat of solution measurements included within it, and gives  $3858.4$  and  $1.4 \text{ J mol}^{-1}$  for the best unbiased estimate and standard error of  $(\Delta H_s^\circ)_e$ , the standard enthalpy of dissolution of sodium chloride in water at  $25^\circ\text{C}$ .

Table 13 presents individual estimates and standard errors derived from the respective data set biases and weights from the model. The values are in good agreement with those given by Parker<sup>4</sup> and indicate agreement of the dilution enthalpies. The standard error estimates reflect the agreement of the data set measurements between themselves and with the whole regression model. The model shows that the earlier<sup>4</sup> best value of  $3883 \text{ J mol}^{-1}$  for  $\Delta H_s^\circ$  at  $25^\circ\text{C}$  is significantly too high by 18 standard errors, and that value<sup>12,92</sup> of  $3820 \text{ J mol}^{-1}$  is significantly too low by  $-28$  standard errors.

Table 14 presents the best unbiased estimates from the model of  $\Delta H_s^\circ$  and its standard error from  $0$  to  $100^\circ\text{C}$ . The estimates of the standard error remain relatively small at  $0$  and  $100^\circ\text{C}$  because of the good agreement within the model between the heat of dilution and the heat capacity measure-

<sup>b</sup> Reference 92.

<sup>c</sup> Reference 12.

ments. Columns four and five show the deviations of literature values of  $\Delta H_s^\circ$  from our regression model.

In column four, the deviations of the values of Criss and Cobble<sup>92</sup> are all negative, vary systematically with temperature, are large near  $0^\circ\text{C}$ , decrease to a minimum at  $45^\circ\text{C}$ , thence increase in magnitude to a maximum at  $95^\circ\text{C}$ . Over the whole temperature range the mean deviation is  $-134 \text{ J mol}^{-1}$  ( $-40$  standard errors) and the root-mean-squared deviation is  $164 \text{ J mol}^{-1}$  (45 standard errors). Because of these large and very significant deviations from the consensus of many other reliable calorimetric studies,<sup>73-91,93-113,121,122,125</sup> it is concluded that the measurements of Criss and Cobble<sup>92</sup> contain some systematic error.

In column five of Table 14, the deviations of the model of Pitzer, Bradley, Rogers, and Peiper<sup>12</sup> are entirely similar to those of column four, and vary systematically from  $0$  to  $100^\circ\text{C}$  with a mean deviation of  $-118 \text{ J mol}^{-1}$  ( $-34$  standard errors) and root-mean-squared deviation of  $148 \text{ J mol}^{-1}$  (37 standard errors). Similarity of the deviations in columns five and four reflects their common origin, because Pitzer *et al.*,<sup>12</sup> between  $0$  and  $100^\circ\text{C}$ , included only the heat of solution measurements of Criss and Cobble.<sup>92</sup> The most recent model by Pitzer, Peiper, and Busey<sup>136</sup> was heavily based on the evaluated enthalpy data of Parker,<sup>4</sup> already discussed.

#### 4.5. Heat Capacity Data

In Table 15 are shown the best unbiased estimates from our model of the partial molal heat capacity of aqueous sodium chloride at infinite dilution  $C_{p,2}^\circ$ , together with its stan-

dard error between 0 and 100 °C. The small values of the standard error given by the model reflect both the wealth of modern heat capacity measurements<sup>98-113,125</sup> between 1.5 and 140 °C and the strongly linked effect of their substantial agreement with the many accurate heat of dilution measurements<sup>73-84</sup> between 0.2 and 150.5 °C. Columns four to nine list the deviations of the literature values<sup>4,12,92,110,112,125</sup> of  $C_{p,2}^{\circ}$  from our regression model.

The deviations in column four of the table, derived from heat of solution values,<sup>92</sup> vary significantly and systematically with temperature, are large and positive between 0 and 30 °C (52 standard errors at 20 °C), decrease to zero near 45 °C, and become large and negative between 50 and 100 °C (-56 standard errors at 80 °C). These deviations of  $C_{p,2}^{\circ}$  from the model are so large and so significant, with root-mean-squared deviation of 6.6 J mol<sup>-1</sup> K<sup>-1</sup> (34 standard errors), that we are forced to conclude that the original  $C_{p,2}^{\circ}$  values<sup>92</sup> contain some systematic error.

The large deviations from -8.9 to 5.1 J mol<sup>-1</sup> K<sup>-1</sup> in columns five<sup>4</sup> and six<sup>112</sup> reflect the lack of accuracy of the older measurements of  $C_{p,\phi}$  at low molalities using batch-calorimeters, together with the large uncertainty of long extrapolations from high molalities to infinite dilution. The considerably smaller deviations from -2.3 to 1.2 J mol<sup>-1</sup> K<sup>-1</sup> in columns seven<sup>110</sup> and eight<sup>125</sup> indicate the better precision of modern flow microcalorimetry at low molalities and the more certain extrapolations to infinite dilution.

Column nine of Table 15 shows the deviations of those  $C_{p,2}^{\circ}$  values calculated by Pitzer *et al.*<sup>12</sup> The relative devia-

tions are significant and positive of 22 and 23 standard errors at 10 and 20 °C, are negative and just significant of -11 standard errors at 30 °C, increase to an extremum of -85 standard errors at 80 °C, and thence decrease to -30 standard errors at 100 °C. Over the temperature range 0 to 100 °C the root-mean-squared deviation of those<sup>12</sup>  $C_{p,2}^{\circ}$  values from the model is 7.5 J mol<sup>-1</sup> K<sup>-1</sup>, corresponding to 44 standard errors.

The  $C_{p,\phi}$  values of Parker<sup>4</sup> at 25 °C agree with the model only at high molality between 6.0 and 1.0*m*, show increasing negative deviations between 1.0 and 0.1*m*, and show an almost constant deviation of -6 J mol<sup>-1</sup> K<sup>-1</sup> (about -50 standard errors) below 0.1*m*. The consensus of the modern flow-calorimeter measurements<sup>103,105,106,109,110,125</sup> make it probable that the  $C_{p,\phi}$  values of Parker at 25 °C are incorrect below 0.1*m*. Corresponding deviations of the  $C_{p,\phi}$  values<sup>4</sup> at 15 °C are consistently positive and 4 to 9 J mol<sup>-1</sup> K<sup>-1</sup> (21 to 80 standard errors), and at 30 °C are consistently negative and -1 to -11 J mol<sup>-1</sup> K<sup>-1</sup> (-10 to -110 standard errors). Since the model fits the measurements<sup>106,125</sup> at 15 and 35 °C to better than 0.2 J mol<sup>-1</sup> K<sup>-1</sup>, the tabulated values<sup>4</sup> of  $C_{p,\phi}$  at 15 and 30 °C are almost certainly in error.

#### 4.6. Standard Gibbs Energy of Solution

The regression model gives -9038.7 and 3.6 J mol<sup>-1</sup> for the best unbiased estimate and standard error of  $(\Delta G_s^{\circ})_0$ , the standard Gibbs energy change for crystalline sodium chloride dissolution in water at 25 °C. The large estimate of the standard error derives mainly from the uncertainty of the

activity coefficient since the solubility uncertainty is smaller by a factor of 3. Standard thermodynamic function changes for salt dissolution at other temperatures are given in Table 34.

#### 4.7. NBS Tables of Chemical Thermodynamic Properties

The recently published<sup>135</sup> NBS tables of chemical thermodynamic properties for sodium chloride at 25 °C provide modern values for comparison with our model. The standard partial molal heat capacity<sup>135</sup> deviates from our model by  $-6.0 \text{ J mol}^{-1} \text{ K}^{-1}$  ( $-50$  standard errors). The standard changes of Gibbs energy, enthalpy, and entropy for sodium chloride dissolution<sup>135</sup> deviate from our model estimates in Table 34 by  $44 \text{ J mol}^{-1}$  (12 standard errors),  $25 \text{ J mol}^{-1}$  (18 standard errors), and  $0.113 \text{ J mol}^{-1} \text{ K}^{-1}$  (9 standard errors), respectively. The deviations exhibited by the standard partial molal heat capacity, the standard enthalpy change for dissolution and by the enthalpies of dilution are identical with those of Parker,<sup>4</sup> already discussed. For the process of sodium chloride dissolution, the deviation of the standard Gibbs energy change<sup>135</sup> relative to our model arises mainly from the deviation of the standard enthalpy change<sup>4</sup> together with a large deviation from the difference of the saturation activity coefficient, for which the value of Hamer and Wu<sup>6</sup> is too small. Numerically the  $44 \text{ J mol}^{-1}$  deviation of the standard Gibbs energy change<sup>135</sup> is comprised of (i) a  $25 \text{ J mol}^{-1}$  deviation of the standard enthalpy change,<sup>4</sup> (ii) a  $16 \text{ J mol}^{-1}$  deviation from the different activity coefficient<sup>6</sup> at saturation, and (iii) a  $3 \text{ J mol}^{-1}$  deviation from the different saturation solubility.<sup>6</sup>

### 5. Thermodynamic Property Estimates from the Regression Model

#### 5.1. Auxiliary Properties of Water

The boiling point and the vapor pressure of the solution, given in Tables 18 and 21, respectively, were calculated from the osmotic coefficient, the nonideality of water vapor,<sup>115</sup> and the vapor pressure of pure water. The vapor pressure of water at temperatures up to 100 °C was calculated from Eq. (15) of Wexler.<sup>129</sup> Above 100 °C the water vapor pressure was calculated from the equation of Osborne and Meyers<sup>130</sup> using parameters from Bain.<sup>131</sup> Before substitution into this equation, temperatures were converted to IPTS-48.

The specific heat of the solution and the partial molal heat capacity of water, given in Tables 26 and 28, respectively, were calculated from the model in conjunction with values for the heat capacity of pure water. The heat capacity of water for temperatures up to 100 °C was derived from the values of de Haas, quoted by Stimson.<sup>132</sup> Temperatures were converted to IPTS-68 and the heat capacity values were also adjusted for the change of temperature scale. The resulting specific heat values were fitted by a polynomial in relative temperature variable  $d = (t_{\text{IPTS-68}} - 25)$  to give the equation

$$\begin{aligned} c_p(\text{J kg}^{-1} \text{ K}^{-1}) \\ = 4180.133 - 3.663 385 E - 01 d + 2.303 039 E - 02 d^2 \\ - 5.446 535 E - 04 d^3 + 1.255 068 E - 05 d^4 \\ - 1.942 578 E - 07 d^5 + 1.793 303 E - 09 d^6 \\ - 7.007 329 E - 12 d^7 \end{aligned} \quad (56)$$

for the specific heat of water up to 100 °C.

For temperatures above 100 °C, the heat capacity of water was derived from enthalpy values between 100 and 200 °C of Osborne, Stimson, and Ginnings,<sup>133</sup> and enthalpy values at 70, 80, and 90 °C of Osborne, Stimson, and Fiock.<sup>134</sup> The enthalpy values were converted from international to absolute joules and the temperatures were converted to IPTS-68. The resulting enthalpies were fitted by a polynomial in  $d$ , defined above, and the resulting enthalpy equation was differentiated with respect to temperature to give

$$\begin{aligned} c_p(\text{J kg}^{-1} \text{ K}^{-1}) = 4170.251 + 1.595 764 E - 01 d \\ + 2.824 609 E - 03 d^2 \\ + 4.133 199 E - 05 d^3 \end{aligned} \quad (57)$$

for the specific heat of water at saturation pressure above 100 °C.

#### 5.2. Property Estimates for Sodium Chloride Brines

Model estimates and their standard errors for some commonly used thermodynamic properties of brine are presented in Tables 16 to 32. Part A of these tables defines the solution composition in molality units (mol NaCl/kg H<sub>2</sub>O), part B in wt.% NaCl. The number of digits retained corresponds with up to two significant digits on the standard error. The standard error reflects only the uncertainty propagated from the deviations of the brine measurements from the model. The corresponding thermodynamic properties of the pure components water and sodium chloride are taken as known and error free.

Tables 16 A and 16 B give the freezing point and its standard error for sodium chloride solutions saturated with air at atmospheric pressure; the freezing point of salt-free water under the same conditions is taken as 0.000 °C. Freezing temperatures are increased by 0.010 °C in the absence of dissolved gas at water saturation pressure.

Tables 17 A and 17 B give the solubility of sodium chloride and its standard error for air-saturated solutions at atmospheric pressure between 0 and 109 °C.

Tables 18 A and 18 B give the boiling point and its standard error for sodium chloride solutions at water saturation pressures between 80 and 120 kPa. The maximum boiling temperature and composition of the salt-saturated brines are given and denoted SAT.

Tables 19–32 present model estimates and standard errors for thermodynamic properties of sodium chloride solutions under conditions of low pressure (water saturation pressure to 101.325 kPa) over the temperature range 0–110 °C. The table number, the thermodynamic property, and symbol used in the text are listed as follows:

Table	Thermodynamic property, text symbol
19	practical osmotic coefficient, $\phi$
20	ionic mean molal activity coefficient, $\gamma$
21	water saturation vapor pressure of brine, $p_1$
22	apparent molal relative enthalpy of sodium chloride, $L_\phi$
23	partial molal relative enthalpy of water, $L_1$
24	partial molal relative enthalpy of sodium chloride, $L_2$
25	integral heat of solution of sodium chloride, $\Delta H_s$
26	specific heat of brine (per kg solution)
27	apparent molal heat capacity of sodium chloride, $C_{p,\phi}$
28	partial molal heat capacity of water, $C_{p,1}$
29	partial molal heat capacity of sodium chloride, $C_{p,2}$
30	apparent molal relative heat capacity of sodium chloride, $C_{p,\phi} - C_{p,2}$

- 31 partial molal relative heat capacity of water,  $J_1$   
 32 partial molal relative heat capacity of sodium chloride,  $J_2$ .

The integral heat of dilution of sodium chloride brine to infinite dilution,  $\Delta H_d(m \rightarrow 0)$ , has the opposite sign but the same magnitude as the apparent molal relative enthalpy given in Table 22.

The deviations with temperature of the standard thermodynamic functions for aqueous sodium chloride from their values at reference temperature 25 °C [ $G_2^\circ - (G_2^\circ)_\theta$ ,  $H_2^\circ - (H_2^\circ)_\theta$ ,  $C_{p,2}^\circ - (C_{p,2}^\circ)_\theta$ , and  $S_2^\circ - (S_2^\circ)_\theta$ ] are presented in Table 33.

The standard thermodynamic function changes for dissolution of crystalline sodium chloride in water [ $G_c^\circ - G_e$ ,  $H_c^\circ - H_e$ ,  $C_{p,2}^\circ - C_{p,c}^\circ$  and  $S_c^\circ - S_e^\circ$ ] and their errors at temperatures up to 110 °C are given in Table 34.

## 6. Conclusion

A model of the Pitzer type has been successfully extended to accurately represent the equilibrium Gibbs energy measurements and the calorimetric enthalpy and heat capacity measurements for aqueous sodium chloride below 154 °C. The model parameters have been evaluated by the weighted least-squares technique using a new and objective method to define the statistical weights of the measurements. The fit of the model to the measurements is limited by the disagreement between the various discordant sets of measurements and not by the ability of the model to represent any particular set.

The regression model with 35 parameters (given in Table 5) is found to be optimal and is the unbiased estimator of minimum variance for 2428 brine measurements between -21 and 154 °C. This data set contains most of the prominent and modern thermodynamic measurements for sodium chloride solutions at low pressure published before 1982. Thus the model is probably the most efficient unbiased estimator for the thermodynamic properties of aqueous sodium chloride up to 101.325 kPa pressure over the temperature range -21 to 100 °C.

Model estimates and standard errors have been presented for the thermodynamic properties of sodium chloride brines at low pressure for temperatures up to 110 °C.

## 7. Acknowledgments

The authors wish to acknowledge discussions with R. H. Wood who kindly provided prepublication data, discussions with the late G. S. Kell, and assistance from C. M. Criss, J. E. Desnoyers, and G. Perron, L. G. Hepler, F. J. Millero, K. S. Pitzer, R. F. Platford, R. W. Potter II, A. H. Truesdell, and W. A. Van Hook. We are indebted to D. M. Young for editorial assistance.
