Energy Levels of Copper, Cu I through Cu xxix

Jack Sugar and Arlene Musgrove

Center for Atomic, Molecular, and Optical Physics, National Measurement Laboratory,
National Institute of Standards and Technology, Gaithersburg, MD 20899

Received August 2, 1989; revised manuscript received February 15, 1990

The energy levels of the copper atom, in all stages of ionization for which experimental data are available, have been compiled. Ionization energies, either experimental or theoretical, and experimental g-factors are given. Leading components of calculated eigenvectors are listed.

Key words: atomic; copper; energy levels; ions; spectra.

1. Introduction

In 1952 Moore published a compilation of energy levels of copper containing the results of extensive analyses of Cu I through Cu III along with six levels of Cu XIX (Na-like). Today, we have energy levels for most stages of ionization of Cu and very accurate calculated levels for Li-, He-, and H-like ions. The new experimental data were obtained with light sources such as the sliding spark, low inductance triggered spark, laser, tokamak, and beam-foil, most of which were unheard of in 1952.

The present critical compilation of the atomic energy levels of copper in all stages of ionization is part of an ongoing program of the NIST (formerly NBS) Atomic Energy Levels Data Center to compile similar data for all the elements. Our recent publications include helium by Martin [1973, 1987], sodium, magnesium, aluminum,

and silicon by Martin and Zalubas (1981, 1980, 1979, 1983), and phosphorus by Martin, Zalubas, and Musgrove (1985), potassium through nickel by Sugar and Corliss (1985), molybdenum by Sugar and Musgrove (1988), and lanthanum through lutetium by Martin, Zalubas, and Hagan (1978).

A companion work containing all published wavelengths of Cu X through Cu XXIX is in preparation in collaboration with the Japanese Atomic Energy Research Institute at Tokai-Mura. Similar works for titanium by Mori *et al.* (1986) and iron, nickel, and molybdenum by Shirai *et al.* (1987a, 1987b, 1990) have been published. The strong lines of Cu I to Cu V are contained in the *CRC Handbook of Chemistry and Physics*, "Line Spectra of the Elements," edited by Reader and Corliss (1989). A compilation published by Kelly (1987) gives classifications and all wavelengths of copper ions below 2000 Å.

In the present work all energy levels are given in units of cm⁻¹. An estimate of the uncertainty of the energy level values or wavelengths determining them is usually given with each ion. This is reflected in the number of

significant figures given for the levels. Ionization energies are also given in eV with the conversion factor 8065.5410(24) cm⁻¹/eV published by Cohen and Taylor [1987]. These values are usually derived from Rydberg series by the authors or by us from their data. Where series data are not available we have used ionization-energy values obtained by Lotz [1967] by isoelectronic extrapolation. These have an accuracy of about 1.0%, as estimated from comparisons with experimental values.

We have included under the heading "Leading percentages" the results of calculations that express the eigenvector percentage composition of levels (rounded to the nearest percent) in terms of the basis states of a single configuration, or more than one configuration where configuration interaction has been included. We give first the percentage of the basis state corresponding to the level's name; next the second largest percentage together with the related basis state. Generally, when the leading percentage is less than 40%, no name is given. When the first and second resultant terms are the same but have different percentages, and their share of the eigenvector composition sums to 40% or more, the level is named as the higher percentage term. In cases where these percentages differ by one or two percent (an insignificant difference), either term may be selected for the level name, and the lower percentage may appear first. For an unnamed level, the term symbol for the leading percentage follows the percentage. The user should of course bear in mind that the percentages are model dependent, so that the results of different calculations can yield notably different percentages.

For configurations of equivalent *d*-electrons, several terms of the same *LS* type may occur. These are theoretically distinguished by their seniority number. In our compilations they are designated in the notation of Nielson and Koster [1963]. For example, in the 3*d*⁵ configuration there are three ²D terms with seniorities of 1, 3, and 5. These terms are denoted as ²D1, ²D2, and ²D3 respectively, by Nielson and Koster.

We use without comment notations for various coupling schemes as appropriate. Martin, Zalubas, and Hagan [1978] give a complete summary of the coupling notations used here. Tables of the allowed terms for equivalent electrons, etc.

The text for each ion does not include a complete review of the literature but is intended to credit the major contributions. In assembling the data for each spectrum, we referred to the following bibliographies:

- i. Papers cited by Moore (1952)
- ii. C. E. Moore (1969)
- iii. L. Hagan and W. C. Martin (1972)
- iv. L. Hagan (1977)
- v. R. Zalubas and A. Albright (1980)
- vi. A. Musgrove and R. Zalubas (1985)

vii. Bibliographic file of publications since December 1983 maintained by the NIST Atomic Energy Levels Data Center.

3. Tables of Energy Levels

Cu I

 $\ell = 29$ Ground state $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} 4s^2 S_{1/2}$ Ionization energy $62\ 317.44 \pm 0.10\text{ cm}^{-1}$ ($7.726\ 380 \pm 0.000\ 012\text{ eV}$)

Shenstone's [1948] analysis of this spectrum, with wavelengths in the range of 1504 to 18 229 Å, provides the energy levels $3d^{10}4s$ to $9s$, $4p$ to $11p$, $4d$ to $11d$, $4f$ and $5f$, as well as $3d^94s^2$, $4s4p$, $4s5p$, $4s5s$ to $4s8s$, and $4s4d$ to $4s6d$. All levels built on the $3d^9$ core are above the first ionization limit except $4s^2$ and $4s4p$. Shenstone recognized the coupling of $3d^94s4p$ as $3d^9(^2D) + 4s4p(^1P)$, a scheme that is found to apply in general to $3d^94s4p$ configurations. Shenstone fit the very regular 2S and 2D series to extended Ritz formulas. However he found that the 2P series is strongly perturbed by the $3d^9(^2D)4s4p(^1P) ^2P$ term, causing considerable displacement of the $3d^{10}np$ series and inverted 2P terms. The percentage compositions of the $3d^94s4p$ levels are given by Martin and Sugar [1969], who included configuration interaction with $3d^84s^24p$. They also provided unpublished percentages for $3d^94s5s$.

Absorption spectra in the range of 1146–1633 Å were observed by Tondello [1973] using flash-pyrolysis supplemented by observations with an inductively heated furnace. He extended the $3d^{10}np$ series to $n=31$ and reported several series of the type $3d^94snp$ and nf . The series $3d^94snp\ ^4P_{3/2}$, $^4P_{1/2}$, and $^2P_{1/2}$ show strong autoionization effects (broad Fano profiles) due to mixing with the $3d^{10}4p\ ^2P$ continuum. The broadest line of the spectrum is assigned to $3d^{10}4s\ ^2S_{1/2} - 3d^94s5p\ ^2P_{3/2}$ but no other member of this series is identified. A series tentatively identified as $3d^{10}4s(^1D_2)np\ ^2P_{1/2,3/2}$ is sharp but would be expected to mix strongly with the continuum. We have assigned J,j -coupling terms where possible because they are more clearly associated with the limits given by Tondello. His LS names for the series are also included. The $(^3D_2)nf$ and $(^3D_1)nf$ series have no unique term designations. This is also true of the $(^3D_1)np$ series in J,j -coupling, although Tondello has given LS -designations.

For $(^3D_3)4f$ and $(^3D_1)5f$ the author gave two lines each because he was unable to select between them.

The $3d^94s(^1D)np\ ^2P$ series is tentatively identified. Tondello notes that this series is sharp and that there is no doubt about the limit.

Longmire *et al.* [1980] obtained high resolution absorption data using a King furnace and a 6.6-m vacuum spectrograph in second and third orders of the grating. They observed the forbidden series $3d^{10}4s - 3d^{10}ns$ for $n=20-41$ and the electric quadrupole series $4s - nd$ for $n=4-8$. The $3d^{10}np$ series was extended to $n=57$. We use their results where they improve the accuracy of previous measurements, as well as their value for the ionization energy. Most of the measurements of Longmire *et al.* have an uncertainty of $\pm 0.10\text{ cm}^{-1}$ while those of Tondello are $\pm 0.7\text{ cm}^{-1}$. Each long term series observed in absorption has been grouped by series rather than interspersed by level value in numerical order.

The g -values given to three and four places are from Blachman *et al.* [1969], and the remaining ones are from Sommer [1926], Shenstone [1926], and Beals [1926].

Ni I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^6 3d^{10} \text{ } ^1\text{S}_0$ Ionization energy $163\ 669.2 \pm 0.5 \text{ cm}^{-1}$ ($20.292\ 40 \pm 0.000\ 06 \text{ eV}$)

Shenstone [1936] carried out the major analysis of this spectrum with observations of 1350 lines from 600 to 10 200 Å. A review of the earlier work is given in this reference. Shenstone gave *LS*-coupling names to almost all the levels. However, many of the $3d^9nl$ configurations are clearly in *jl*-coupling and we have used that notation for $3d^9nf$ and $3d^9ng$. The $3d^9ns$ levels ($n = 5-10$) are given *jj*-coupling designations.

The odd configurations $3d^94p$ and $(3d^95p + 3d^96p + 4d^84s4p)$ were calculated by Roth [1969] in *LS*-coupling, the latter with configuration interaction. We have given the theoretical designations for these levels and Roth's *jl*-coupling assignments for the configurations $3d^94f$ and $5f$.

Reader, Meissner, and Andrew [1960] reported interferometric measurements of 61 Cu II lines in the region 1979 to 2885 Å with an uncertainty of $\pm 0.001 \text{ \AA}$. With these data, relative level values for $3d^94p$, $3d^94s$, and $3d^95s$ were established. From infrared grating observations by Carter [1948] accurate values were extended to levels of $3d^95p$ and $3d^96s$. With these level values (38 in all) 66 wavelengths between 983 and 1663 Å were calculated with an accuracy of $\pm 0.0005 \text{ \AA}$.

Kaufman and Ward [1966] measured three resonance transitions (at 1358 Å, 1367 Å, and 1472 Å) from the three $J=1$ levels of the $3d^94p$ configuration. Using as reference standards the calculated Cu II wavelengths of Reader *et al.* in the second order they obtained a level uncertainty of $\pm 0.03 \text{ cm}^{-1}$.

A more extensive set of interferometric and grating measurements of Cu II was reported by Ross [1969]. He extended the analysis with about 90 new levels and resolved close levels of the $3d^95g$ configuration. The new determinations for all the levels have uncertainties of $\pm 0.03 \text{ cm}^{-1}$. We have rounded his four-place level values to three places. Two levels from Shenstone established with one line each were not confirmed. They are given here to one decimal place.

The Zeeman effect for Cu II was observed by Shenstone [1927] and by Lott, Roos, and Ginter [1966]. The *g*-values from Shenstone's observations were calculated by Moore [1952].

The ionization energy was obtained by Ross [1969] from the *ns*, *nd*, and *nf* series. We quote his average for 12 series.

 $Z = 29$

Co I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^6 3d^9 \ ^2D_{5/2}$ Ionization energy $297\ 140 \pm 100\ \text{cm}^{-1}$ ($36.841 \pm 0.012\ \text{eV}$)

The early work on this spectrum is summarized by Shenstone and Wilets [1951] where much of the low structure is given. New observations by Shenstone [1975] with pulsed hollow cathode and sliding-spark light sources produced a line list covering the range of 500–5820 Å, measured to three decimal places, and 5821–6852 Å, measured to two decimal places. With this improved line list the levels of $3d^9$, $3d^84s$, and $3d^84p$ were redetermined and completed with the addition of the levels based on the $3d^1S$ parent. Following this, all but one level of $3d^84d$ and most levels of $3d^85d$ were found. In addition, levels of $3d^84f$, $3d^74s^2$, $3d^85s - 7s$, $3d^85p$, and $3d^85g$ were identified. Six levels identified as $3d^74s4p$ were not assigned term designations, but were

given numerical names. The percentage compositions of most of the levels have been calculated by Sugar and Martin [1976], and their designations for the levels have been adopted.

The ionization energy was derived by Shenstone from the ns series.

Cu IV

 $Z=29$

Fe I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^6 3d^8 {}^3F_4$ Ionization energy $462\ 800 \pm 400\text{ cm}^{-1}$ ($57.38 \pm 0.05\text{ eV}$)

The earlier analysis of Cu IV by Schröder and van Kleef [1970] has been superseded by the analyses by Meinders [1976] and Meinders and Uijlings [1980]. Meinders [1976] reobserved the spectrum using a sliding spark light source. She carefully separated lines of various ionization stages by comparing spectra taken at various peak currents. The analysis led Meinders to find all nine levels of $3d^8$, 37 of the 38 levels of $3d^74s$, and 109 of the 110 levels of $3d^74p$. The level uncertainty is $\pm 1\text{ cm}^{-1}$.

New spectrograms were made by Meinders and Uijlings [1980] to obtain better exposures of the transition arrays $3d^74p - 3d^74d$ and $3d^74p - 3d^75s$. Additional measurements in the known arrays permitted a correction to the positions of the known levels. Downward shifts of 0.3 cm^{-1} for the $3d^74p$ levels and 1.7 cm^{-1} for the $3d^74s$ levels were recommended with respect to those published by Meinders [1976]. In addition, 27 lev-

els of $3d^75s$ and 113 levels of $(3d^74d + 3d^64s^2)$ were found.

Percentage compositions were given by Meinders [1976] for the $3d^8$, $3d^74s$, and $3d^74p$ configurations. Meinders and Uijlings [1980] gave percentages for $3d^7(4d + 5s) + 3d^64s^2$.

An experimental value for the ionization energy was derived from $3d^7ns$ series. It agrees within 0.5% with the extrapolated value given by Lotz [1967].

Cu V ($^4F_{9/2}$)	<i>Limit</i>		462 800	

Cu v $Z = 29$ **Mn I** isoelectronic sequenceGround state $1s^2 2s^2 2p^6 3s^2 3p^6 3d^7 {}^4F_{9/2}$ Ionization energy $644\,000 \pm 6000 \text{ cm}^{-1}$ ($79.8 \pm 0.7 \text{ eV}$)

The first work on Cu v was reported by van Kleef, Joshi, and Benschop [1975] who found the 4F term of $3d^7$ and the 6P , 4D , and 4F terms of $3d^6({}^5D)4p$.

New observations of this spectrum were obtained by van Kleef, Raassen, and Joshi [1976]. They identified the $3d^7 - 3d^64p$ array in the region $270 - 410 \text{ \AA}$ and the $3d^64s - 3d^64p$ array in the region $1100 - 1330 \text{ \AA}$. All levels of the $3d^7$ were reported as well as 53 of the 63 levels of the $3d^64s$ and 175 of the 180 levels of $3d^64p$. The uncertainty of the level values is $\pm 3 \text{ cm}^{-1}$. Percentage compositions were obtained for these configurations

without taking into account configuration interaction between $3d^7$ and $3d^64s$.

The value for the ionization energy was obtained by Lotz [1967] by extrapolation.

 $Z=29$

Cr I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^6 3d^6 \ ^5D_4$ Ionization energy $831\,000 \pm 8000 \text{ cm}^{-1}$ ($103 \pm 1 \text{ eV}$)

The initial line identifications in this spectrum were the $3d^6 - 3d^5(^6S)4p \ ^5P^o$ multiplet found by Poppe *et al.* [1974]. A considerable extension was made by Raassen and van Kleef [1981] using new exposures of a sliding spark discharge. They reported an analysis of the $3d^6 - 3d^54p$ array that produced all levels of $3d^6$, except for the highest 1S_0 , and 208 of the 214 levels of $3d^54p$. They also analyzed the $3d^54s - 3d^54p$ array and found 13 of the 74 levels of $3d^54s$. The level accuracy is estimated to be $\pm 1.5 \text{ cm}^{-1}$. The percentage compositions for all the levels were calculated by these authors without tak-

ing into account configuration interaction between $3d^6$ and $3d^54s$.

The value for the ionization energy was derived by Lotz [1967] by extrapolation.

Cu VII**Z=29****V I isoelectronic sequence**Ground state $1s^2 2s^2 2p^6 3s^2 3p^6 3d^5 \ ^6S_{5/2}$ Ionization energy $1\ 120\ 000 \pm 8000 \text{ cm}^{-1}$ ($139 \pm 1 \text{ eV}$)

The $3d^5 \ ^6S - 3d^4 4p \ ^6P^o$ multiplet was identified in the spectrum of a spark discharge by Kruger and Gilroy [1935].

The value for the ionization energy was obtained by Lotz [1967] by extrapolation.

ReferencesKruger, P. G., and Gilroy, H. T. [1935], Phys. Rev. **48**, 720.Lotz, W. [1967], J. Opt. Soc. Am. **57**, 873.van het Hof, G. J., Raassen, A. J. J., Uylings, P. H. M., Joshi, Y. N., Podobedova, L. I., and Ryabtsev, A. N. [1990], Phys. Scr. **41**, 240.*Note added in proof:*

A new analysis of this spectrum by van het Hof et al. [1990] appeared too late for inclusion in the present compilation. They determined all 37 levels of the $3d^5$ ground configuration and 129 of the 180 possible levels of the $3d^4 4p$ configuration.

 $Z=29$

Ca I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^6 3d^2 {}^3F_2$ Ionization energy $1\ 870\ 000 \pm 16\ 000\ \text{cm}^{-1}$ ($232 \pm 2\ \text{eV}$)

Alexander *et al.* [1966] reported the transition array $3d^2 - 3d4f$. New observations by Even-Zohar and Fraenkel [1968] led to additional classified lines and improved wavelengths with an accuracy of $\pm 0.005\ \text{\AA}$ in the range of $86 - 88\ \text{\AA}$.

Fawcett *et al.* [1980] provided measurements and classifications of the $3p^6 3d^2 - 3p^5 3d^3$ array in the range of $132 - 154\ \text{\AA}$ with an uncertainty of $\pm 0.007\ \text{\AA}$. Two lines classified as transitions to the unknown term $3d^2 {}^1G$ could not be used here.

We estimated the position of the $3d^2 {}^1D_2$ level by extrapolation with an uncertainty of $\pm 200\ \text{cm}^{-1}$. All levels followed by “+x” are dependent on the 1D_2 level value.

The value for the ionization energy was obtained by Lotz [1967] by extrapolation.

K I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^6 3d^2 D_{3/2}$ Ionization energy $2\ 140\ 000 \pm 2000\ \text{cm}^{-1}$ ($265.3 \pm 0.2\ \text{eV}$)

Alexander *et al.* [1965] identified the resonance doublet $3p^6 3d^2 D - 3p^6 4f$ at $78\ \text{\AA}$. This was remeasured and the series extended by Even-Zohar and Fraenkel [1968] with a measurement uncertainty of $\pm 0.01\ \text{\AA}$.

The transition array $3p^6 3d - 3p^5 3d^2$ was first analyzed by Goldsmith and Fraenkel [1970] from spectra obtained with a triggered spark source. Their estimated wavelength uncertainty of $\pm 0.005\ \text{\AA}$ was found to be an order of magnitude too small by Ramonas and Ryabtsev [1980] who remeasured the spectrum in the range of $108 - 184\ \text{\AA}$ with a reported uncertainty of $\pm 0.003\ \text{\AA}$. Their improved analysis of this array and newly discovered $4p^2 P^o$ levels are quoted here.

Levels of the $3p^5 3d 4s$ configuration were found by Hoory *et al.* [1970]. They identified the transitions to the

ground 2D term in the range of $72 - 76\ \text{\AA}$, which they measured with an uncertainty of $\pm 0.005\ \text{\AA}$.

We derived the value for the ionization energy from the three-member nf series.

Ground state $1s^2 2s^2 2p^6 3s^2 3p^6 \text{ } ^1\text{S}_0$ Ionization energy $2975000 \pm 30000 \text{ cm}^{-1}$ ($369 \pm 4 \text{ eV}$)

Goldsmith and Fraenkel [1970] reported the $3p^6 \text{ } ^1\text{S} - 3p^5 3d \text{ } ^1\text{P}^\circ$ resonance line at $139.180 \pm 0.005 \text{ \AA}$ from a spark discharge. It was later observed in a tokamak plasma by Sugar, Kaufman, and Rowan [1987] who gave the value $139.174 \pm 0.005 \text{ \AA}$ and reported an interpolated value for the $3p^6 \text{ } ^1\text{S} - 3p^5 3d \text{ } ^3\text{D}_1$ line of $174.739 \pm 0.010 \text{ \AA}$. The results of Sugar *et al.* are quoted, including their calculation of the percentage compositions.

Even-Zohar and Fraenkel [1968] added the $3p^6 \text{ } ^1\text{S}_0 - 3p^5 4s$ and $4d$ resonance lines with an uncertainty of $\pm 0.01 \text{ \AA}$.

Swartz *et al.* [1975] give the transition array $3p^5 3d - 3p^5 4f$, but these lines are not connected to the known lower levels.

The value for the ionization energy was obtained by Lotz [1967] by isoelectronic extrapolation.

Cl I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^5 {}^2P_{3/2}$ Ionization energy $3\ 234\ 000 \pm 30\ 000\ \text{cm}^{-1}$ ($401 \pm 4\ \text{eV}$)

The magnetic dipole (M1) transition between the levels of the ${}^2P^o$ ground term was observed in a tokamak plasma by Hinnov *et al.* [1982] at $3500.4 \pm 0.3\ \text{\AA}$.

Sugar and Kaufman [1986] reported several lines of the $3p^5 - 3p^4 3d$ array observed in a laser-generated plasma. Following a study of the Cl I isoelectronic sequence, Kaufman, Sugar, and Rowan [1988] revised the analysis and gave the levels reported here. In a later revision by Kaufman and Sugar [1989] the level $3s^2 3p^4 {}^3P 3d {}^2P_{1/2}$ was removed and an interpolated value was given. The ground term splitting is obtained from the M1 transition with an uncertainty of $\pm 2\ \text{cm}^{-1}$. All the other lev-

els have an uncertainty of $50\ \text{cm}^{-1}$.

The value for the ionization energy was obtained by Lotz [1967] by isoelectronic extrapolation.

S I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^4 {}^3P_2$ Ionization energy $3\ 508\ 000 \pm 30\ 000\ \text{cm}^{-1}$ ($435 \pm 4\ \text{eV}$)

Two magnetic dipole lines, giving the intervals $3s^2 3p^4 {}^3P_2 - {}^3P_1$ and ${}^3P_1 - {}^1S_0$, were observed by Roberts *et al.* [1987] in a tokamak plasma at $4183.4 \pm 0.3\ \text{\AA}$ and $1190.4 \pm 0.5\ \text{\AA}$, respectively. The latter establishes the relative position of the singlet system. We include the predicted value for the 3P_0 level from the calculation of Sugar and Kaufman [1984]. The uncertainty in this prediction is about $\pm 100\ \text{cm}^{-1}$.

An analysis of the configurations $3s 3p^5$ and $3s^2 3p^3 3d$ was given by Sugar and Kaufman [1986]. Revisions have been made by Kaufman, Sugar, and Rowan [1990] in a study of the isoelectronic sequence. We compiled the results of the latter work.

The value for the ionization energy was obtained by Lotz [1967] by isoelectronic extrapolation.

P 1 isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^3 \text{ } ^4\text{S}_{3/2}^o$ Ionization energy $3\ 903\ 000 \pm 40\ 000 \text{ cm}^{-1}$ ($484 \pm 5 \text{ eV}$)

Two magnetic dipole lines, giving the intervals $3s^2 3p^3 \text{ } ^4\text{S}_{3/2}^o - \text{ } ^2\text{D}_{3/2}^o$ and $\text{ } ^4\text{S}_{3/2}^o - \text{ } ^2\text{P}_{3/2}^o$, were observed by Denne *et al.* [1984] in a tokamak plasma at 2085.3 ± 0.2 and $944.6 \pm 0.2 \text{ \AA}$, respectively. The $\text{ } ^2\text{P}_{1/2}^o$ energy is a calculated value by Sugar and Kaufman [1984].

Fawcett and Hayes [1975] classified two transitions between $3s^2 3p^3$ and $3s^2 3p^2 3d$, the $\text{ } ^2\text{D}_{5/2}^o - \text{ } ^3\text{P}_2^o$ and $\text{ } ^4\text{S}_{3/2}^o - \text{ } ^3\text{P}_2^o$ lines. These were confirmed in a subsequent analysis of the spectrum of a laser-generated plasma by Sugar and Kaufman [1986]. The latter authors reported an additional seven levels of $3s^2 3p^2 3d$. Hutton *et al.* [1987] used a beam-foil apparatus to reobserve this spectrum. They classified 9 lines of the $3p^3 - 3p^2 3d$ array, revising the analysis of Sugar and Kaufman. Their results are quoted here with levels based on improved wavelength measurements from the line list of Sugar and Kaufman. They also reported 3 lines arising from the $3s 3p^3$ configuration. We found that they do not fit their isoelectronic sequences, and that one of them, at 296.6 \AA , is a second order line.

The uncertainty of the levels of the ground configuration is $\pm 20 \text{ cm}^{-1}$, except for the predicted value for $\text{ } ^2\text{P}_{1/2}^o$. This value was obtained from the fitted calculation of the $3p^3$ configuration. We estimate the uncertainty to be $\pm 100 \text{ cm}^{-1}$. The uncertainty of the levels of $3s 3p^4$ is also about $\pm 20 \text{ cm}^{-1}$, and that of $3s^2 3p^2 3d$ is about $\pm 60 \text{ cm}^{-1}$.

The value for the ionization energy was obtained by Lotz [1967] by isoelectronic extrapolation.

 $Z=29$

Si I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^2 {}^3P_0$ Ionization energy $4\ 194\ 000 \pm 40\ 000\ \text{cm}^{-1}$ ($520 \pm 5\ \text{eV}$)

All the levels of the $3s^2 3p^2$ ground configuration are determined from magnetic dipole lines in tokamak plasmas. The transitions ${}^3P_0 - {}^3P_1$, ${}^3P_2 - {}^1D_2$, and ${}^3P_1 - {}^1S_0$ were observed by Denne *et al.* [1983] and the ${}^3P_1 - {}^1D_2$ transition was observed by Hinnov [1985] and Roberts *et al.* [1987]. The ${}^3P_2 - {}^1D_2$ line was tentatively identified at 2539.7 Å. Datla *et al.* [1989] have revised this to a line they observed at 2544.7 ± 0.5 Å.

The 5S_2 level of the $3s 3p^3$ configuration was determined by Träbert *et al.* [1987] from beam-foil observations of transitions to the ground term. The remaining levels of $3s 3p^3$ and those of $3s^2 3p 3d$ were derived by Sugar and Kaufman [1986] from spectra of a laser-generated plasma. Improved wavelengths and new level values were given by Sugar, Kaufman and Rowan [1990] and are used here. The uncertainty of these level values is $\pm 25\ \text{cm}^{-1}$. The percentage compositions are from their calculations which included configuration interaction between $3s 3p^3$ and $3s^2 3p 3d$.

Both Kastner *et al.* [1978] and Khan [1978] investigated $n=3-4$ transitions, identifying transitions $3p^2 - 3p 4d$ and $3p 3d - 3p 4f$. Khan also reported several

lines of $3p^2 - 3p 4s$. These data provided the levels given here (some questionable ones were omitted) with an uncertainty of $\pm 5000\ \text{cm}^{-1}$.

The value for the ionization energy was obtained by Lotz [1967] by isoelectronic extrapolation.

 $Z = 29$

Al I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 3p^2 P_{1/2}^0$ Ionization energy $4\ 493\ 000 \pm 48\ 000\ \text{cm}^{-1}$ ($557 \pm 6\ \text{eV}$)

The ground $^2P^0$ term interval was obtained from the magnetic dipole transition observed in a tokamak plasma at $3007.6 \pm 0.3\ \text{\AA}$ by Hinnov *et al.* [1982].

The 4P term of $3s 3p^2$ was given by Träbert, Heckmann, Hutton, and Martinson [1988], who used beam-foil excitation to observe the transitions $3s^2 3p^2 P^0 - 3s 3p^2 ^4P$. Sugar, Kaufman, and Rowan [1988] reported the multiplet $3s 3p^2 ^4P - 3p^3 ^4S$. We used the data of Träbert *et al.* to derive the $^4P_{5/2}$ level and the more accurate data of Sugar, Kaufman, and Rowan to determine the 4P intervals. The latter authors also gave the rest of the levels of $3s 3p^2$ and the $3s^2 3d ^2D$ term. We use the levels derived by them from smoothed wavelengths for the isoelectronic sequence. The level uncertainty is $\pm 50\ \text{cm}^{-1}$. The percentage compositions were calculated by them with configuration interaction between $3s 3p^2$ and $3s^2 3d$.

Three levels of the $3s 3p 3d$ configuration are derived from the classifications of lines by Buchet-Poulizac and Buchet [1988] and the more accurate wavelengths of Sugar and Kaufman (private communication).

Khan [1978] obtained $n = 3-4$ transitions in the range of $42-51\ \text{\AA}$ with an accuracy of $\pm 0.02\ \text{\AA}$ by means of a laser-generated plasma. The level uncertainty is $\pm 1000\ \text{cm}^{-1}$.

The value for the ionization energy was obtained by Lotz [1967] by isoelectronic extrapolation.

 $Z = 29$

Mg I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2 1S_0$ Ionization energy $5\ 105\ 000 \pm 48\ 000\ \text{cm}^{-1}$ ($633 \pm 6\ \text{eV}$)

Fawcett and Hayes [1975] classified five lines of this spectrum, including the $3s^2 1S_0 - 3s3p 1P_1$ resonance line. The configurations $3s3p$, $3p^2$, and $3p3d$ were completed by Sugar and Kaufman in a series of papers [1986a, 1986b, 1987]. The level uncertainty is $\pm 50\ \text{cm}^{-1}$. In the last paper they caution that the wavelengths in the first two papers should be lowered by $0.02\ \text{\AA}$. The level interval $3s3p 1P_1 - 3P_2$ was observed directly with the magnetic dipole line at $3941.6 \pm 0.3\ \text{\AA}$ by Denne *et al.* [1983]. The percentage compositions of the levels were given by Litzén and Redfors [1987] with configuration interaction within the $3s^2$, $3s3d$, and $3p^2$ even and the $3s3p$ and $3p3d$ odd configurations.

The 3F_4 and 1G_4 levels of the $3d^2$ configuration were found by Redfors [1988] in an isoelectronic study of the spectra calcium through zinc. Sugar *et al.* [1989] identified the 3F_3 and 3F_2 levels of $3d^2$.

With a high voltage spark Feldman *et al.* [1971] produced and identified the transition arrays $3s3d - 3s4f$ and $5f$, $3s3p - 3s4s$, $3s3p - 3s4d$ and $3s5d$, and the resonance line $3s^2 1S_0 - 3s4p 1P_1$. These wavelengths fall in the range of $30 - 49\ \text{\AA}$ and are measured with an accuracy of $\pm 0.01\ \text{\AA}$. Using a similar light source Kastner *et al.* [1978] found the $3p3d - 3p4f$ array occurring at $49 - 51\ \text{\AA}$. We assume the same wavelength accuracy of

$\pm 0.01\ \text{\AA}$ from the author's general remarks. The level uncertainty for these two groups of levels is $\pm 600\ \text{cm}^{-1}$ and $\pm 400\ \text{cm}^{-1}$.

Swartz *et al.* [1971] identified the resonance transition from the $2p^5 3s^2 3d 1P_1$ autoionizing level at $11.774\ \text{\AA}$.

The value for the ionization energy was obtained by Lotz [1967] by isoelectronic extrapolation.

Na I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s\ ^2S_{1/2}$ Ionization energy $5\ 408\ 660 \pm 250\ \text{cm}^{-1}$ ($670.588 \pm 0.003\ \text{eV}$)

The $3d - 4f$ doublet was first given by Edlén [1936]. Several more doublets were reported by Feldman, Cohen, and Swartz [1967] and considerably extended by Feldman *et al.* [1971]. New measurements were given by Kononov, Ryabtsev, and Churilov [1979] who improved the accuracy of the $n=3-3$ transitions and added the $4p - 5d$, $4d - 5f$, and $4f - 5g$ doublets. We use their measurements to determine all levels for $n > 3$ except for $6p$, $7d$, $8d$, $4f$, and $7f$, which were given only by Feldman *et al.* [1971]. Reader *et al.* [1987] derived least-squares adjusted wavelengths for the $3s - 3p$, $3p - 3d$, and $3d - 4f$ multiplets along the Na I isoelectronic sequence. We use their values to find the $3s$, $3p$, $3d$, and $4f$ levels. Uncertainties in the level values are as follows: for $n=3 \pm 15\ \text{cm}^{-1}$, for $n=4 \pm 300\ \text{cm}^{-1}$, for $n=5 \pm 1000\ \text{cm}^{-1}$, and for $n=6-8 \pm 2000\ \text{cm}^{-1}$.

A line at $13.11\ \text{\AA}$ classified as the transition from the autoionizing level $2p^5 3s^2\ ^2P_{3/2}$ to the ground state was reported by Feldman and Cohen [1967] with an uncertainty of $\pm 6000\ \text{cm}^{-1}$. Jupén *et al.* [1988] observed a line at $210.70 \pm 0.05\ \text{\AA}$ in a beam foil experiment, which they

classified as the transition $2p^5 3s 3p\ ^4D_{5/2} - 2p^5 3s 3d\ ^2F_{5/2}$ from experimental and theoretical isoelectronic studies. We have neither of these levels from which to derive the other.

The value for the ionization energy was derived by Kononov *et al.* from core-polarization theory applied to the $5g$ term.

Ne I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 \ ^1S_0$ Ionization energy $13\ 630\ 000 \pm 140\ 000\ \text{cm}^{-1}$ ($1697 \pm 17\ \text{eV}$)

The resonance transitions from the $2s^2 2p^5 3s$, $2s^2 2p^5 3d$, and $2s^2 2p^5 3p$ configurations were identified in a spark discharge by Feldman, Cohen, and Swartz [1967]. Feldman and Cohen [1967] reported the two resonance lines from $2s^2 2p^5 4d$. Swartz *et al.* added the resonance lines from $2s^2 2p^5 4s$, $5d$, and $6d$. All these resonance lines were given with improved accuracy of $\pm 0.003\ \text{\AA}$ by Boiko, Faenov, and Pikuz [1978].

New observations of this sequence from Fe to Br were published by Gordon, Hobby, and Peacock [1980]. Their wavelengths for Cu in the range of 8 to $13\ \text{\AA}$ agree within a few thousandths \AA with those of Boiko *et al.* Their calculations show that the transition $2s^2 2p^6 - 2s^2 2p^5 (^2P_{1/2}) 4s$ given previously as $9.423\ \text{\AA}$ should be replaced with the line $9.375\ \text{\AA}$. They have given additional resonance lines arising from the levels $2s^2 2p^5 4d$ ($^3/2, ^3/2$) $_1^o$, and $2s^2 2p^5 4p$ ($^1/2, ^1/2$) $_1^o$, and ($^1/2, ^3/2$) $_1^o$. We use an average of the wavelengths from the two sets of measurements.

The wavelengths and analysis of the $2p^5 3s - 2p^5 3p$ and $2p^5 3p - 2p^5 3d$ arrays were given by Buchet *et al.* [1987].

They observed these data in the range of $215 - 380\ \text{\AA}$ with beam-foil excitation, and reported a wavelength uncertainty of $\pm 0.05\ \text{\AA}$ for the strong, well-resolved lines and $\pm 0.1\ \text{\AA}$ for the remaining lines. Their level values are given relative to the lowest $2p^5 3s J=1$ level as reference.

The value for the ionization energy was derived by Lotz [1967] by extrapolation.

 $Z=29$

F 1 isoelectronic sequence

Ground state $1s^2 2s^2 2p^5 {}^2P_{3/2}^o$ Ionization energy $14\ 550\ 000 \pm 150\ 000\ \text{cm}^{-1}$ ($1804 \pm 18\ \text{eV}$)

The splitting of the ${}^2P^o$ ground term was determined by Kononov *et al.* [1977] with their identification of the doublet $2s^2 2p^5 {}^2P^o - 2s 2p^6 {}^2S$ at $78.388(10)\ \text{\AA}$ and $90.353(10)\ \text{\AA}$ in a laser-produced plasma. We use the more accurate value obtained from the measurement by Hinnov *et al.* [1982] of the magnetic dipole transition $2s^2 2p^5 {}^2P_{3/2}^o - {}^2P_{1/2}$ at $592.3 \pm 0.3\ \text{\AA}$ observed in a tokamak discharge.

The $2p^5 - 2p^4 3s$ and $3d$ arrays were observed by Boiko *et al.* [1979], by Gordon *et al.* [1980], and by Hutcheon *et al.* [1980a] in the range of $10.8\ \text{\AA}$ to $12.2\ \text{\AA}$ using laser-produced plasmas. The reported wavelengths were in close agreement. We therefore use average values and estimate an uncertainty of $\pm 0.003\ \text{\AA}$. Gordon *et al.* also give the $2s^2 2p^5 - 2s 2p^5 3p$ array in the range of 9.9 to $10.4\ \text{\AA}$.

Buchet-Poulizac and Buchet [1988], using beam-foil excitation, have identified the $2p^4 3s - 2p^4 3p$ and $2p^4 3p - 2p^4 3d$ transitions in the range of $168.82 \pm 0.5\ \text{\AA}$ to $346.25 \pm 0.5\ \text{\AA}$. Those transitions involving known levels are used to determine the $2p^4 3p$ levels and the two $J = 7/2$ levels of $2p^4 3d$.

The $2p^5 - 2p^4 4s, 4d$ arrays were observed by Hutcheon *et al.* [1980b] and by Gordeon *et al.* at $\sim 8.5\ \text{\AA}$.

They are mostly blends and are not suitable for deriving energy levels.

The percentage compositions of the even levels were given by Chapman and Shadmi [1973].

The value for the ionization energy was derived by Lotz [1967] by isoelectronic extrapolation.

Ground state $1s^2 2s^2 2p^4 {}^3P_2$ Ionization energy $15\ 450\ 000 \pm 150\ 000\ \text{cm}^{-1}$ ($1916 \pm 19\ \text{eV}$)

Two magnetic dipole lines within the ground configuration, the ${}^3P_2 - {}^3P_1$ at $657.7 \pm 0.3\ \text{\AA}$ and the ${}^3P_2 - {}^1D_2$ at $420.0 \pm 0.3\ \text{\AA}$, were observed in a tokamak discharge by Hinnov *et al.* [1982].

The transition array $2s^2 2p^4 - 2s 2p^5$ was first given by Kononov *et al.* [1977], and was extended by Behring *et al.* [1985]. The $2s 2p^5 {}^1P_1 - 2p^6 {}^1S_0$ line was first given by Peregudov *et al.* [1978]. Additional lines were found by Ekberg *et al.* [1987] who reobserved the spectrum in the range of $65 - 115\ \text{\AA}$ with a wavelength uncertainty of $\pm 0.015\ \text{\AA}$. The energy levels are quoted from Ekberg *et al.* with their uncertainty of $\pm 200\ \text{cm}^{-1}$.

Observations of the $2p^4 - 2p^3 3d$, $4s$, $4d$ arrays were given by Gordon *et al.* [1980] in the range of $8 - 12\ \text{\AA}$. Their data do not appear to be sufficiently resolved for reliable analysis.

The value for the ionization energy was derived by Lotz [1967] by isoelectronic extrapolation.

N I isoelectronic sequence

Ground state $1s^2 2s^2 2p^3 {}^4S_{3/2}^o$ Ionization energy $16\ 620\ 000 \pm 160\ 000\ \text{cm}^{-1}$ ($2060 \pm 20\ \text{eV}$)

Three M1 transitions within the ground configuration have been observed. They are the ${}^4S_{3/2}^o - {}^2D_{3/2,5/2}$ lines at $434.8 \pm 0.3\ \text{\AA}$ and $585.0 \pm 0.3\ \text{\AA}$ by Hinnov *et al.* [1982] and the ${}^2D_{3/2} - {}^2D_{5/2}$ line at $1691.0 \pm 0.3\ \text{\AA}$ by Hinnov [1985].

Transitions of the $2s - 2p$ type were observed and classified by Kononov *et al.* [1977] and Behring *et al.* [1985] using laser-produced plasmas. A more complete excitation of these arrays was produced by Ekberg *et al.* [1987], who found all the levels of the $2s^2 2p^3$, $2s 2p^4$, and $2p^5$. We use the M1 lines of Hinnov *et al.* [1982] and Hinnov [1985] to derive the levels of $3p^3 {}^2D^o$. The remaining levels are derived from the wavelengths of Ekberg *et al.*

The value for the ionization energy was derived by Lotz [1967] by isoelectronic extrapolation.

C I isoelectronic sequence

Ground state $1s^2 2s^2 2p^2 {}^3P_0$ Ionization energy $17\,600\,000 \pm 180\,000 \text{ cm}^{-1}$ ($2182 \pm 22 \text{ eV}$)

Two M1 lines observed in a tokamak plasma determine the ground configuration levels, except for 1S_0 . The transitions ${}^3P_0 - {}^3P_1$ and ${}^3P_1 - {}^3P_2$ were reported by Hinnov *et al.* [1982] at $756.9 \pm 0.3 \text{ \AA}$ and $1776.0 \pm 0.3 \text{ \AA}$, respectively. The same authors measured two more M1 lines that determine the position of the 1D_2 level, the transitions ${}^3P_1 - {}^1D_2$ and ${}^3P_2 - {}^1D_2$ at $414.1(3) \text{ \AA}$ and $540.3(3)$, respectively.

Ekberg *et al.* [1987] determined all but one level, $2p^4 {}^1D_2$, of the $n=2$ complex from the spectrum of a laser-generated plasma.

The ionization energy was derived by Lotz [1967] by isoelectronic extrapolation.

Ground state $1s^2 2s^2 2p\ ^2P_{1/2}^o$ Ionization energy $18\ 620\ 000 \pm 180\ 000\ \text{cm}^{-1}$ ($2308 \pm 22\ \text{eV}$)

The ground term $^2P^o$ splitting was determined with the M1 line at $522.8 \pm 0.3\ \text{\AA}$ classified by Hinnov *et al.* [1982].

Ekberg *et al.* [1987] observed the $2s 2p^2\ ^4P - 2p^3\ ^4S^o$ multiplet. With Edlén's [1983] estimate of the position of $2p^3\ ^4S^o$ we give levels of both terms with " $+x$ " equal to the systematic error.

The ionization energy was derived by Lotz [1967] by isoelectronic extrapolation.

Be I isoelectronic sequence

Ground state $1s^2 2s^2 ^1S_0$ Ionization energy $19\ 986\ 000 \pm 200\ 000\ \text{cm}^{-1}$ ($2478 \pm 24\ \text{eV}$)

Buchet *et al.* [1985] classified ten lines in the range of $111-173\ \text{\AA}$. These are sufficient to derive all the levels of $2s2p$ and $2p^2$ with an uncertainty of $\pm 1000\ \text{cm}^{-1}$. The $2s^2 ^1S_0 - 2s2p\ ^3P_1^o$ intersystem resonance line was observed at $227.80 \pm 0.15\ \text{\AA}$ by Denne and Hinnov [1987].

Spectra in the range of 8.5 to $9.7\ \text{\AA}$ were observed by Boiko *et al.* [1978] and Brown *et al.* [1987], the latter including additional lines at $27\ \text{\AA}$ and the $2s^2 ^1S_0 - 2s2p\ ^1P_1^o$ resonance line at $111.071\ \text{\AA}$. All levels with $n \geq 3$ are derived from the data of Brown *et al.* combined with the levels of Buchet *et al.* The uncertainty of the levels with $n \geq 3$ is $\pm 8000\ \text{cm}^{-1}$. The wavelengths of Brown *et al.* were assigned an uncertainty of $0.005\ \text{\AA}$ for wavelengths below $12\ \text{\AA}$ and $\pm 0.010\ \text{\AA}$ for those above.

New measurements of the resonance lines from $2s2p\ ^3P_1^o$ and $^1P_1^o$ were obtained by Hinnov at $227.808 \pm 0.01\ \text{\AA}$ and $111.186 \pm 0.01\ \text{\AA}$ and quoted by Denne *et al.* [1989]. The $2s2p\ ^3P_1^o - ^3P_2^o$ interval was observed with the M1 transition at $648.0 \pm 0.2\ \text{\AA}$ by Hinnov *et al.* [1982].

The ionization energy was derived by Lotz [1967] by isoelectronic extrapolation.

Li I isoelectronic sequence

Ground state $1s^2 2s \ ^2S_{1/2}$ Ionization energy $20\ 870\ 000 \pm 10\ 000\ \text{cm}^{-1}$ ($2587.5 \pm 1.2\ \text{eV}$)

Knize *et al.* [1987] measured the $2s - 2p$ doublet in a tokamak plasma, and obtained the wavelengths $224.770 \pm 0.008\ \text{\AA}$ and $153.508 \pm 0.005\ \text{\AA}$, giving a level uncertainty for $2p \ ^2P^o$ of $\pm 20\ \text{cm}^{-1}$. Transitions from more highly excited one-electron states were observed in a laser-generated plasma by Brown *et al.* [1987]. The uncertainty of levels derived from these lines is $\pm 10\ 000\ \text{cm}^{-1}$. Aglitskii and Panin [1985] reported two lines from doubly excited states $1s2p3p$ and $1s2p4p$, observed in a spark discharge. Their level uncertainty is $\pm 15\ 000\ \text{cm}^{-1}$. Lie and Elton reported the resonance transition from the $^2P^o$ term of $1s2s2p$.

The value for the ionization energy was obtained by Brown *et al.* using core polarization formulas. Its uncer-

tainty is based on the uncertainty of the $3d$, $4d$, and $4f$, levels from which it is derived.

He I isoelectronic sequence

Ground state $1s^2 \ ^1S_0$ Ionization energy $89\ 224\ 060 \pm 5000\ \text{cm}^{-1}$ ($11\ 062.38 \pm 0.62\ \text{eV}$)

Observations of the transition $1s^2 \ ^1S_0 - 1s2p \ ^1P_1$ are reported in the following papers:

Lie and Elton [1971]	$1.484 \pm 0.005\ \text{\AA}$
Turechek and Kunze [1975]	$1.4780 \pm 0.0010\ \text{\AA}$
Aglitskii and Panin [1985]	$1.478 \pm 0.003\ \text{\AA}$
Morita and Fujita [1985]	$1.4778 \pm 0.0004\ \text{\AA}$
Aglitsky <i>et al.</i> [1988]	$1.47758 \pm 0.00007\ \text{\AA}$

Drake [1988] reports a calculated value of $1.477587(2)\ \text{\AA}$ for this line.

Turechek and Kunze were able to resolve the $1s^2 - 1s2p \ ^3P_{1,2}$ levels at the wavelengths $1.4840 \pm 0.0005\ \text{\AA}$ and $1.4805 \pm 0.0010\ \text{\AA}$, respectively. Transitions from $1s3p$ and $1s4p \ ^1P_1$ to the ground state were given by Aglitskii and Panin.

We give calculated values by Drake [1988] for the $1s2s$ and $1s2p$ levels and the ionization energy. His estimated level uncertainty is $\pm 85\ \text{cm}^{-1}$. We adopt an uncertainty of 5 parts in 10^5 representing the approximate difference between the best observations in this region of the sequence (see, e.g., Beiersdorfer *et al.* [1989], and Drake [1988]). Drake's $n=2$ levels are $43 \pm 14\ \text{cm}^{-1}$

lower than those circulated privately by Drake in 1985, which included levels of the $n=3$ shell. We include the latter reduced by $43\ \text{cm}^{-1}$.

Buchet *et al.* [1985] measured the energy of the transition $1s2s \ ^3S_1 - 1s2p \ ^3P_2$ as $483\ 910 \pm 200\ \text{cm}^{-1}$. Drake's calculation gives the energy as $483\ 663\ \text{cm}^{-1}$.

H I isoelectronic sequence

Ground state $1s^2 S_{1/2}$ Ionization energy $93\ 299\ 090 \pm 30\ \text{cm}^{-1}$ ($11\ 567.617 \pm 0.004\ \text{eV}$)

No measurement of resolved lines of this ion are yet available. We give the theoretical values for the $1s$, $2s$, and $2p$ levels as well as the ionization energy calculated by Johnson and Soff [1985]. The estimated uncertainty of these quantities relative to the ground state is $\pm 30\ \text{cm}^{-1}$, while that of $2p$ $^2P^o$ term splitting is $\pm 2\ \text{cm}^{-1}$. Johnson and Soff's values agree with those calculated by Mohr [1983] within the uncertainties.

For $n=3$ to 5 the values for the energy levels were obtained by subtracting the binding energies calculated by Erickson [1977] from the Johnson and Soff value for the ionization energy. Assuming that the Lamb shift scales as $1/n^3$, we estimate the error in Erickson's calcula-

tions for the ns levels as $8/n^3$ times his error of $310\ \text{cm}^{-1}$ for $2s$. The resulting errors for $3s$, $4s$, and $5s$ are $\pm 90\ \text{cm}^{-1}$, $\pm 40\ \text{cm}^{-1}$, and $\pm 20\ \text{cm}^{-1}$, respectively. For the rest of the levels with $n \geq 3$ we estimate the uncertainty to be $\pm 20\ \text{cm}^{-1}$.
