Wavelengths and Energy Level Classifications for the Spectra of Aluminum (Al I through Al XIII)

Victor Kaufman and W. C. Martin

National Institute of Standards and Technology, Gaithersburg, MD 20899

Received February 20, 1991; revised manuscript received May 28, 1991

Wavelengths and their classifications have been compiled for the spectra of the atom and all positive ions of aluminum ($Z = 13$). The selections of data are based on the compilations of energy levels by Martin and Zalubas [1979, J. Phys. Chem. Ref. Data **8**, 817–864], with some updating from the more recent literature. Wavelengths (or wavenumbers) calculated from the differences of the energy levels are given along with the observed values for all classified lines; these calculated wavelengths should in general be more accurate than the observed values wherever the two values differ significantly. Calculated wavelengths are also given for a number of lines that have not yet been observed, including some important forbidden transitions. The most complete data are given in separate tables for the different spectra. No limitation has been imposed on the wavelength range of the classified lines, except for the omission of x-ray transitions in the neutral atom. Two finding lists are also included, one for Al I through Al III and the other for Al IV through Al XIII.

Key words: aluminum; atomic energy levels; atomic ions; atomic spectra; atomic wavelengths; atomic wavenumbers.

1. Introduction

The Atomic Energy Levels Data Center of the National Institute of Standards and Technology (NIST) publishes critical compilations of atomic energy levels, which have updated and extended the three volumes of *Atomic Energy Levels* by Charlotte Moore [1971]. Martin, Zalubas, and Hagan [1978] compiled energy-level data for spectra of the rare-earth elements lanthanum to lutetium ($Z = 57-71$). New critical compilations of energy-level data have also been published for Na I–XI, Mg I–XII, Al I–XIII, Si I–XIV [Martin and Zalubas, 1981, 1980, 1979, 1983, respectively], P I–XV, and S I–XVI [Martin, Zalubas, and Musgrove, 1985, 1990]. Compilations of the energy levels for all spectra of the iron-peric elements potassium through nickel [Sugar and Corlis 1985] and for Mo I–XLII and Cu I–XXIX [Sugar ar Musgrove, 1988, 1990] have also appeared.

These new compilations review the literature ar provide a basis for assembling a complete list of classifi spectral lines for each stage of ionization. Recently NIS in collaboration with the Japan Atomic Energy Resear Institute, has compiled wavelengths for high-ionizati spectra of iron, nickel, copper, and molybdenum [Shi *et al.*, 1990, 1987a, 1991, 1987b]. Wavelength compi tions for *all* stages of ionization have been published f scandium [Kaufman and Sugar, 1988] and magnesi [Kaufman and Martin, 1991].

We have used the aluminum energy-levels compi tions by Martin and Zalubas [1979], supplemented some more recent publications, to compile the lists classified lines given here. The energy levels were used predict wavenumbers and wavelengths for compari with the directly measured values.

Reprints available from ACS; see Reprints List at back of issue.

Wavelengths (or wavenumbers) calculated from the fferences of the energy levels are given along with the served values for all classified lines. *Unless otherwise ted, the calculated wavelengths should in general be more curate than the observed values wherever the two values fer significantly*. The upper energy levels for some tran-ions were rounded off to fewer significant figures than ere given for the observed wavelengths, in order to rep-sent the uncertainties of the data more realistically; any fferences between such observed wavelengths and val-s calculated from the rounded-off energy levels are in neral insignificant. In a few cases, needed reevalua-ons of particular energy levels on the basis of more re-nt measurements have not yet been carried out; and in me cases we tabulate two or more experimentally re-lved hyperfine-structure components belonging to a ngle calculated transition. The greater accuracy or reso-tion of the pertinent observed wavelengths is men-oned in such cases.

The most complete data are given in thirteen separate bles, one for each spectrum (ionization stage). No lim-ation has been imposed on the wavelength range of the assified lines, except for the omission of x-ray transi-ons in the neutral atom. In addition to electric-dipole ansitions, we have tabulated "forbidden" lines from agnetic-dipole or electric-quadrupole transitions.

Some observed lines are classified as unresolved blends f two or more transitions. We list the calculated wave-ngth for each of the main components of such a blend r, in some cases, the calculated wavelength of the prob-ble strongest component.

Calculated wavelengths are given for a substantial umber of lines that have not yet been observed, includ-g both allowed and important forbidden transitions. he calculated wavelengths for (helium-like) Al XII and ydrogen-like) Al XIII were derived from theoretically lculated levels, since their estimated accuracy is greater an the accuracy of levels based on the available mea-rements. We have significantly extended the wave-ngth tables for both of these spectra by including lculated wavelengths for a relatively large number of as t unobserved lines.

At the beginning of the table for each spectrum, e give the isoelectronic sequence, the ground tate, and the ionization energy (the divisor 065.5410 ± 0.0024 cm^{-1}/eV has been used to convert avenumber values to eV units [Cohen and Taylor, 987]). A list of references is also given with each table. *ur comments on the data and references are supplementary the information given by Martin and Zalubas [1979]; this eference is hereafter abbreviated as "MZ79" and is omitted om the reference lists for the individual tables.*

The format of the tables is similar to that adopted by Kelly [1987]. The comments below follow the sequence of he columns in the tables.

Mult. No.

The multiplet numbers are those assigned by Moore [1950, 1959].

Relative Intensity

The numbers are usually visual estimates related in some way to plate blackening. Some authors limit these estimated to a small range (e.g., 1 to 10) while others reach into the 100,000's. Such numbers are useful within a small wavelength range and are meaningful only for comparing lines of a particular spectrum as taken from a particular reference. More meaningful relative intensities obtained with photoelectric or solid-state detectors are given by some authors, especially for observations in the infrared region. We have in some cases adjusted the intensities in particular regions to reduce apparent discrepancies between different observers, etc. Kelly [1987] adjusted the various intensity scales of the original observers to a normalized scale having a maximum intensity of 1000. For some spectra, we give Kelly's adjusted intensities for some or all of the lines below 2000 Å. We use the following symbols to further characterize the lines:

M1, M2, E2, ... magnetic-dipole, magnetic-quadrupole, electric-quadrupole, ... transition

bl blended with another line that may affect the wavelength and intensity

m masked by another line (no wavelength measurement)

d diffuse, wide, hazy, etc.

g transition involving a level of the ground term

a observed in absorption

Wavelength

Vacuum wavelengths are given for the region below 2000 Å and wavelengths in standard air for the region 2000 – 10 000 Å. The data are tabulated in order of increasing wavelengths. Both the observed and calculated wavelengths are given for the classified lines, the calculated values being obtained from the energy-levels differences. A question mark following a calculated wavelength indicates that the energy-levels classification of the line is questionable. We converted vacuum wavelengths or wavenumbers to wavelengths in air using the three-term formula of Peck and Reeder [1972] for the index of refraction of air.

Wavenumber

Vacuum wavenumbers are given instead of wavelengths for lines having wavelengths greater than 10 000 Å (1000 nm). The lines are listed in order of decreasing wavenumber, and both the observed and calculated values are given for classified lines.

Levels

The numerical values of the two levels for the transition. The values of levels obtained from theoretical calculations are enclosed in brackets. A question mark following the upper level indicates that the classification is tentative.

Configurations, Terms, and *J* Values

These data for the two levels are given in successive columns. The configuration and term notations are described fully by Martin *et al*. [1978]. Levels having incomplete theoretical designations are indicated by blank spaces in one or more of the columns. A blank *J* value may also indicate that the corresponding level value represents two or more unresolved levels. A fully interpreted level lacking an appropriate configuration and/or term designation because of a strongly mixed eigenvector composition is indicated by the symbol " $\langle\psi|$ " in the corresponding column(s).

Ref.

The letter-numerical symbols indicate references listed at the beginning of the table. The references in this column are for the *observed* wavelength values only. If two or more references are listed for a single observed wavelength, the value is usually a weighted average.

The tables for the individual spectra are followed by two finding lists. Section 3 contains the lines of Al I through Al III and Section 4 contains the lines of Al IV through Al XIII. This separation is intended to follow roughly the division of user interests. The two finding lists include only wavelengths, intensities, and spectrum symbol. The wavelengths in the finding lists are observed values unless otherwise indicated: wavelengths calculated from experimental energy levels are followed by the letter "*c*", and calculated wavelengths involving theoretical o series-formula levels are given in brackets.

2. Tables of Wavelengths and Energy Level Classifications

Al I

Ground state $1s^2 2s^2 2p^6 3s^2 3p\ ^2P^o_{1/2}$

Ionization energy 48 278.480 ± 0.025 cm^{-1} (5.985 771 ± 0.000 003 eV)

As noted in MZ79, components of the $3s3p^2\ ^2D$ term contribute to the eigenvectors of the $3s^2nd\ ^2D$ series members so that most of the $3s3p^2\ ^2D$ composition is distributed amongst the first few members of the series. This absorption of the $3s3p^2\ ^2D$ term by the $3s^2nd$ series leads to a mislabeling of the higher $3s^2nd$ members if the lower ^2D terms are assigned $3s^2nd$ names in the unbroken sequence $n = 3,4,5,\ldots$. We have here avoided this mislabeling by designating the former $3s^24d\ ^2D$ term as "$y\ ^2D$" and reducing by unity the n values of all the previous $3s^2nd\ ^2D$ terms having $n \geq 5$. *This change must be taken into account in comparing the classifications of transitions involving the* $3s^2nd\ ^2D$ *levels given here with those in the previous literature and also with the levels tabulated in* MZ79.

Ericksson and Isberg [E1] gave their measurements of the $3s^23p - 3s^24s$ and $3s^23p - 3s^23d$ resonance wavelengths to four decimal places, although the observed lines are complicated by hyperfine spreads of ~0.03 to ~0.05 cm^{-1} for the levels involved. We have listed four-place calculated wavelengths for the lower $3p - nd$ and $3p - ns$ series members (2169 – 3962 Å), in part to indicate their higher accuracy relative to other lines in this region. Paschen's [P4] measurements of weakly recorded lines have apparent errors up to ± 0.06 Å.

The observations of the higher $3p - ns$ and $3p - nd$ series members are described in MZ79. We have recalculated the 10*s* through 16*s* levels using a new series formula (see below). The energy levels for some of the higher $nd\ ^2D$ terms in MZ79 were derived entirely from Yamashita's measurements [Y1] because of an apparent systematic error in the results of [P3]; we nevertheless give averaged values for the "observed" wavelengths in the region where the two sets of observations overlap.

The infrared observations by Biémont and Brault [B1] cover the range 8884 – 1866 cm^{-1}, the apparent wavenumber uncertainty being a few units in the third decimal place for most of the lines. Biémont and Brault located the $3s^25g$, $6g$, $7g$, and $7h$ doublet terms, and Chang [1990] used the new infrared data of [B1] to reevaluate the levels in the range from $3s^23d$ through $3s^27h$. The corresponding level values adopted here are mostly from Chang's results, the main exceptions being that we have included measurements from [E1] in evaluating the $3s^23d$ and $3s^26f$ levels. We have omitted the hyperfine structures included in Chang's evaluations of the $3s^2ns$, np, and nd levels; for some transitions we thus list the experimental wavenumbers for two or more resolved hyperfine components [B1] along with a single calculated wavenumber.

We have also reevaluated the $3s3p(^3P^o)nd\ ^2D^o$ levels using the new $3s^2nd\ ^2D$ level values. The re $3s3p(^3P^o)3d\ ^2D^o$ levels have Ritz-principle consis justifying three decimal-place values. We also give place values for the $3s3p^2\ ^2P$ levels, based on the ir transitions $3s3p^2\ ^2P - 3s3p(^3P^o)3d\ ^2D^o$ [E1]. Th four-place Ritz-principle calculated wavelengths for the $3s^23p\ ^2P^o - 3s3p^2\ ^2P$ lines (1763 – 1769 probably accurate within ± 0.001 Å.

The $3s^2ng$ and $7h$ terms are connected to the $3s^$ ground term through accurate measurements of v infrared transitions [B1, B4; see Chang, 1990] ar $3s^23p - 3s^24s$ resonance doublet [E1]. We obtain ionization energy given above by fitting the $3s^25g$, and $7h$ terms to a core-polarization formula wit dipole polarizability, the quadrupole polarizabilit the ionization energy as variable parameters. This for the ionization energy agrees exactly with the Chang obtained by an essentially similar procedure estimated uncertainty is mainly due to the overall u tainty of the connection of the $3s^2ng$ and $7h$ levels the ground term.

We give the calculated wavenumber of the $6h - 7$ (810.706 cm^{-1}), and also the energies for both of levels, as obtained from the polarization formula; ne level is connected experimentally to the other know els.

We have fitted the $3s^2ns$ ($n = 4-9$) and ($n = 3-7$) levels to new Ritz-type series formulae those used in [E1], but with the limit fixed at the n adopted value. Although this adopted limit is 0.11 higher than the value derived in E1 from a fit of th series ($n = 4-6$), we find no unacceptable deviatio any of the *ns* or *np* levels from our formulae.

Zherikhin *et al.* [Z1] used a laser step-excita method to observe $3d - nf$ transitions for $n = 11$ tc (6234 – 6697 Å). We combined their experime wavenumbers for the $3d\ ^2D_{3/2} - nf\ ^2F^o_{5/2}$ and $^2D_{5/2} - nf\ ^2F^o$ transitions with the adopted $3d\ ^2D$ level ues to obtain an average position for each $nf\ ^2F^o$ term. then fitted a three-constant Ritz formula to the entir series ($n = 4-8$, $11-55$) with appropriate rela weights for the different members and allowed the li to vary. This procedure yielded a limit of 48 278.45 cm in reasonable agreement with the value adopted abo The limit we obtain from the *nf* series is 0.03 cm^{-1} ab the value derived by Zherikhin *et al.* [Z1], partly beca our $nf\ ^2F^o$ levels are systematically higher than the val of [Z1] (due to higher $3d\ ^2D$ levels) and partly because include the lower series members with high relat

weights. The 9*f* and 10*f* $^2F^\circ$ levels adopted here were calculated with the new series formula.

The two-place observed wavelengths given for the $3d-nf$ lines ($n=11-55$) were obtained from the corresponding experimental wavenumbers [Z1]. The three-place wavelengths calculated from the levels should on the average be somewhat more accurate. The estimated wavenumber error of $\pm 0.05\ cm^{-1}$ [Z1] corresponds to ± 0.02 Å; somewhat larger discrepancies for some of the $3d-nf$ measurements are indicated by the *nf* series behavior.

Cantù *et al.* [C1] have observed the absorption spectrum in the region near 150 Å and classified 8 of 33 measured lines as arising from L-shell excitation. We give their classifications for four lines; the corresponding upper levels were evaluated by assuming each line to be an unresolved doublet comprising the transitions from both $^2P^\circ_{1/2,3/2}$ ground-term levels. We have omitted multiple classifications for four other lines because the upper levels involved are not experimentally resolved.

Al II

Mg I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s^2\ {}^1S_0$

Ionization energy 151 862.5 ± 0.4 cm^{-1} (18.828 56 ± 0.000 05 eV)

Kaufman and Hagan [K1] estimate an uncertainty of 0.002 Å for their wavelength measurements in the region below 2100 Å. Many of their values are given here to four decimal places to avoid rounding-off errors [K6]. Some of the higher levels given to one decimal place in MZ79 were listed with two-place values in the later publication [K1]; the differences are only marginally significant, and we have used the MZ79 values for most of these levels.

Kaufman and Hagan measured the spectrum up to 8641 Å but did not observe many of the weaker lines given in earlier references [mainly S2 and P1]. Hyperfine-structure components are listed wherever they were experimentally resolved [S2, P1, K1]; of course the calculated wavelengths do not exhibit these hyperfine splittings. We have also included a number of transitions forbidden by the ΔJ and/or ΔF rules [S2, P1].

Biémont and Brault [B1] recorded the infrared spectrum of an aluminum hollow-cathode discharge using a high-resolution Fourier-transform spectrometer. They adopted the $3s5p\ {}^3P^o_0$ position from [K1] and, relative to it, reevaluated twelve other levels from $3s5s\ {}^3S_1$ to $3s6f\ {}^1F^o_3$ on the basis of their data. Their level values are given to three decimal places, but it should be noted that seven of these values represent centers-of-gravity of hyperfine structures having spreads up to 0.5 cm^{-1}. We list here the experimental wavenumbers of all the hyperfine components resolved by [B1] for each transition involving one of these levels; the corresponding calculated wavenumber as obtained from the center-of-gravity level positions shoul be appropriate for comparison with lower-resolution ol servations. Biémont and Brault were also able to locat the $3s6h$, $3s7h$, and $3s7i$ terms.

We obtained a value of 151 862.54 ± 0.08 cm^{-1} for th ionization limit relative to the $3s5g - 13g$, $6h - 9h$, and levels by fitting these levels with appropriate weights to core-polarization formula. This limit agrees with th value 151 862.5 cm^{-1} that Kaufman and Hagan obtaine by fitting the $3sns\ {}^3S$ series. Our estimated error 0.4 cm^{-1} includes the uncertainty of the *ng*, *nh*, *ni* hig angular-momentum system of levels relative to th ground level and the uncertainty of the limit relative this *ng*, *nh*, *ni* system.

Al III

Na I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6 3s\ ^2S_{1/2}$

Ionization energy 229 445.7 ± 0.2 cm^{-1} (28.447 65 ± 0.000 08 eV)

The four-place calculated wavelengths in the region 486 – 1936 Å have estimated errors from 0.0006 Å at the shortest wavelengths to about 0.003 Å at 2000 Å [I1]. We have included calculated wavelengths for all lines tabulated by Isberg, even though many of these lines in the region below 3000 Å have not yet been observed. The calculated wavelengths above 2000 Å are based on Isberg's measurements having estimated errors of about 0.010 Å for the three-place values and 0.03 Å for the two-place values.

Transitions involving levels based on $2p$ excitation have been observed below 200 Å both in emission [F1] and absorption [B5, B6]. Pending further research and compilation of the excited-core levels, we have included here only the stronger and/or more certainly classified of these lines; additional wavelengths are given in the references [F1, B5, B6]. The tabulated lines below 200 Å are classified by upper levels of the excited-core configurations $2p^5 3s^2$, $2p^5 3p^2$, $2p^5 3s 3d$, and $2p^5 3s 3p$. We also include longer-wavelength lines (in the 1192 – 1596 Å range) classified as transitions *within* the excited-core system; these are quartet-system transitions of the $2p^5 3s 3p - 2p^5 3p^2$, $3s 3d$ arrays [G1]. The uncertainties of these longer-wavelength measurements, ±0.08 to ±0.15 Å, correspond to uncertainties of ±10 cm^{-1} or less in the relative positions of the ten quartet levels involved [G1]. We fixed the position of this ten-level group relative to the $2p^6 nl$ single-electron system by using the unblended $2p^6 3p\ ^2P^o_{3/2} - 2p^5 3s 3p\ ^4D_{5/2}, {}^4P_{5/2}$ lines from [F1].

Al IV

Ne I isoelectronic sequence

Ground state $1s^2 2s^2 2p^6\ {}^1S_0$

Ionization energy 967 804 ± 15 cm^{-1} (119.992 ± 0.002 eV)

The best measurements of transitions to the ground level ($\lambda < 162$ Å) are probably accurate to about ± 0.004 Å [K2]. Two-place experimental wavelengths are given for the 476 – 766 Å region; the calculated wavelengths in this region should generally be more accurate, with errors mainly in the range 0.002 to 0.006 Å. Most of the wavelengths above 800 Å have estimated errors of 0.005 to 0.01 Å [K2, A1].

Al v

F I isoelectronic sequence

Ground state $1s^2 2s^2 2p^5\ ^2P^o_{3/2}$

Ionization energy 1 240 684 ± 20 cm^{-1} (153.825 ± 0.003 eV)

The resonance-doublet wavelengths at 278 and 281 Å and the lines measured by Artru and Brillet in the 99 – 190 Å range have estimated uncertainties of 0.002 Å [A2]. The four-place calculated wavelengths (95 – 190 Å) also have uncertainties of about 0.002 Å and "are internally consistent to 0.0005 Å" [A2]. Most of the three-place observed wavelengths above 456 Å have estimated uncertainties smaller than 0.010 Å, and the two-place values have uncertainties mainly between 0.01 and 0.02 Å [A2, B3].

A line observed in the infrared spectrum of Nova Cygni 1975 was classified as the $2s^2 2p^5\ ^2P^o_{3/2} - {}^2P^o_{1/2}$ magnetic-dipole transition in Al v [G2]. The observed wavenumber is 0.9% greater than the predicted value of 3442 ± 3 cm^{-1} but this discrepancy is apparently within the error of the astronomical measurement.

O I isoelectronic sequence

Ground state $1s^2 2s^2 2p^4\ ^3P_2$

Ionization energy 1 536 400 ± 400 cm^{-1} (190.49 ± 0.05 eV)

The measurements of the wavelengths for the $2s^2 2p^4 - 2s 2p^5$ resonance array (221 – 328 Å) are probably accurate within a few thousandths of an Å, and the wavelengths from [A3] for the region below 114 Å have estimated uncertainties of 0.005 Å [B3, A3]. Most of the wavelengths given for the region above 1049 Å are probably accurate to about 0.01 Å [A3].

The values for some of the levels above 1 079 000 cm^{-1} as given in [A3] differ somewhat from the preliminary values given in MZ79; we here adopt the values from [A3].

We derived the ionization energy using two types of formulae to fit the isoelectronic-sequence data (see the energy-levels compilation for P VIII by Martin, W. C., Zalubas, R., and Musgrove, A. [1985], J. Phys. Chem. Ref. Data **14**, 786).

N I isoelectronic sequence

Ground state $1s^2 2s^2 2p^3\ {}^4S^o_{3/2}$

Ionization energy 1 949 900 ± 700 cm^{-1} (241.76 ± 0.09 eV)

We have tentatively included a number of lines classified by upper even-parity levels that were omitted in MZ79. We also list two lines near 280 Å classified as $2s2p^3(^5S^o)3p\ {}^4P - 2s2p^3(^5S^o)4d\ {}^4D$ transitions [V2]; the level assignments here are in better agreement with the observed relative intensities than those in [V2].

Most of the levels were determined by using wavelength averages based on measurements from more than one reference [MZ79]. The calculated wavelengths may thus in general be somewhat more accurate than the observed values quoted from a single reference, even for lines not connected to other lines through the Ritz principle.

We obtained the above value for the Al VIII $2s^2 2p^2\ {}^3P_0$ ionization limit using two types of formulae to fit the isoelectronic-sequence data (see results for S X by Martin, W. C., Zalubas, R., and Musgrove, A. [1990], J. Phys. Chem. Ref. Data **19**, 865). For comparison, we derived values for the $2s^2 2p^2\ {}^3P_2$ limit by fitting Ritz series formulae to two (tentative) three-member series of Al VII, the $2s^2 2p^2(^3P)nd\ {}^2F^o_{7/2}$ and $(^3P)ns\ {}^4P_{5/2}$ series; these gave $^3P_2$ limit values respectively 1270 and 2710 cm^{-1} lower than the $^3P_2$ value consistent with the above $^3P_0$ ionization energy. Additional research is needed on Al VII and other spectra of this sequence in order to decide amongst various possible explanations of such discrepancies.

C I isoelectronic sequence

Ground state $1s^2 2s^2 2p^2\ ^3P_0$

Ionization energy 2 295 900 ± 500 cm^{-1} (284.66 ± 0.06 eV)

Denne and Hinnov classified the $2s^2 2p^2\ ^3P - 2s 2p^3\ ^5S^\circ$ lines at 756.8 and 772.7 Å and thus established the triplet-quintet connection within about ±30 cm^{-1} [D1]. We have reevaluated the quintet levels using their results.

We increased the values of the singlet levels given in [MZ79] by 30 cm^{-1} to obtain better agreement with Edlén's [1985] most recent estimate for the triplet-singlet connection. The value of the $2s^2 2p^2\ ^1D_2$ level tentatively suggested in [D1] would raise the singlet system about 270 cm^{-1} above the estimated position adopted here; the singlet levels are given with an unknown correction "$+x$" to indicate the lack of an experimental confirmation of the connection.

We include lines classified by more than twenty of Ferner's high levels that were omitted in MZ79, the levels being given here as questionable.

Calculated wavelengths are listed for a number of intersystem and magnetic-dipole transitions that have not yet been measured. It is hoped that the absolute value of the unknown quantity "x" is small enough so that the predicted singlet-triplet intercombination wavelengths are useful.

We obtained a value of 2 296 130 cm^{-1} for the ionization energy by applying a semi-empirical isoelectronic correction formula to a theoretically calculated value. Edlén's [1971] ionization-energy formula for this sequence, also based on an isoelectronic treatment of the available data, gives a value of 2 295 650 cm^{-1}. The above value is based on these two results.

B I isoelectronic sequence

Ground state $1s^2 2s^2 2p\ ^2P^o_{1/2}$

Ionization energy 2 662 650 ± 600 cm^{-1} (330.13 ± 0.07eV)

Denne and Hinnov established the quartet-doublet intersystem connection within about ±30 cm^{-1} by classifying two lines near 960 Å as $2s^2 2p\ ^2P^o - 2s 2p^2\ ^4P$ transitions [D1]. We have reevaluated the quartet levels based on their results.

We obtained the ionization energy by fitting a linear Ritz formula to the $2s^2 nd\ ^2D$ series ($n = 3-6$). The above value agrees with the value 2 662 500 ± 300 cm^{-1} derived from this same series by [H1], but our treatment of the data gives a larger standard-deviation error. Our value also agrees satisfactorily with the value 2 662 990 cm^{-1} which we obtained by applying a semi-empirical isoelectronic correction formula to a theoretically calculated value.

Al x

Be I isoelectronic sequence

Ground state $1s^2 2s^2\ ^1S_0$

Ionization energy 3 216 100 cm^{-1} (398.75 eV)

A measurement of the $2s^2\ ^1S_0 - 2s2p\ ^3P_1^\circ$ line at 637.85 Å [D1] gives a value of $x = -21 \pm 30\ cm^{-1}$ for the correction to the triplet level values in MZ79. We have here taken the triplet levels from MZ79 with $x = 0$, which is within the uncertainty of the quoted determination. Several lines in the region below 65 Å are given tentatively as Al X singlet-triplet intercombination transitions. Reevaluations of the data have led to small changes in $2s3d\ ^3D$ and $2s4f\ ^3F^\circ$ levels.

The two features near 7.9 Å were observed by Boiko *et al.* in the spectra of laser-produced plasmas [B5]. These features arise from K-shell excitation, each being classified as a blend of several transitions. The calculated wavelengths were obtained with upper levels based on the theoretical wavelengths from [B5].

We derived a value of 3 215 920 cm^{-1} for the ionization energy by applying a semi-empirical isoelectronic correction formula to a theoretically calculated value. Edlén's [1971] ionization-energy formula for this sequence gives a value of 3 216 300 cm^{-1}. The value given above is based on these results.

Li I isoelectronic sequence

Ground state $1s^2 2s\ ^2S_{1/2}$

Ionization energy 3 564 960 ± 250 cm^{-1} (442.00 ± 0.03 eV)

We have reevaluated the $1s^2 4p$, $4d$, and $4f$ levels using wavelength determinations by Fawcett and Ridgeley [F9]. The $1s^2 4f\ ^2F°$ levels are given in brackets because we fixed their fine-structure separation at the Z-scaled hydrogenic value. The ionization energy is based on the revised $1s^2 4f$ position and a theoretical $4f$ term value [MZ79]. The $1s^2 5d$ and $5f$ levels were evaluated using methods described by Edlén [1979] with the adopted ionization energy; the corresponding calculated wavelengths for the $3p - 5d$ and $3d - 5f$ lines are probably more accurate than the available measurements [J3].

Several features observed between 7.80 and 7.93 Å have been classified as transitions from upper levels of the K-shell excited configurations $1s2s^2$, $1s2s2p$, and $1s2p^2$ [F7, A4, M2]. Since most of these features are blends, we evaluated the upper levels using calculations by Vainshtein and Safronova [1975] and a correction for QED and some smaller contributions not included in their calculations. After reducing the $1s^2 2p - 1s2s^2$, $1s^2 2s - 1s2s2p$ and $1s^2 2p - 1s2p^2$ separations of Vainshtein and Safronova by 1420 cm^{-1}, as an average correction, we derived the $1s2s^2$, $1s2s2p$, and $1s2p^2$ doublet levels by combining these adjusted separations with the $1s^2 2s$ and $1s^2 2p$ levels of MZ79. The $1s2s2p\ ^4P°$ and $1s2p^2\ ^4P$ levels were determined in a similar manner, the level separations being further adjusted to give optimal agreement with measurements of the $1s2s2p\ ^4P° - 1s2p^2\ ^4P$ lines (523 – 542 Å) [B7,T1].

We have also included features classified by transitions from still higher K-shell excited levels assigned to configurations of the type $1s2l3l'$ [A4, B6, F6]. The calculated values given for most of these levels were obtained from theoretical wavelengths [Vainshtein and Safronova, 1980] corrected to include Lamb shifts and adjusted to the values for the lower levels in MZ79.

Al XII

He I isoelectronic sequence

Ground state $1s^2\ ^1S_0$

Ionization energy $16\,824\,529 \pm 250\ cm^{-1}$ $(2085.98 \pm 0.03\ eV)$

The ionization energy and the $1s2l$ levels are theoretical values from Drake [1988]. The other $1snl$ levels are also theoretical values, derived from calculated term values and Drake's ionization energy (see Martin *et al.* [1990] for sources of term values, etc.). The calculated wavelengths for the transitions from upper $1snl$ levels have estimated uncertainties from less than unity to at most a few units in the last decimal place; in most cases the calculated wavelengths are expected to be more accurate than the observed values.

The relative intensities for the $1s^2 - 1snp$ lines are meant only as a rough guide and do not correspond to any specific plasma conditions.

The values of the $2s^2$, $2s2p$, and $2p^2$ levels are based on theoretical calculations by Vainshtein and Safronova [1978], adjusted here to include QED contributions and also for consistency with the adopted $1s2l$ level values. Transitions of the type $1snl - 2l'nl''$ $(n \geq 2)$ from doubly-excited configurations in Al XII give rise to "satellite" features near the Al XIII $1s\ ^2S - 2p\ ^2P^o$ resonance doublet at 7.17 Å. The most prominent of these satellites are due to transitions with $n = 2$; we have included several such features, which lie on the long wavelength side of the Al XIII doublet. Satellite transitions involving configurations with $n \geq 3$ (omitted here) lie nearer the Al XIII doublet and may affect its structure and shape from both the long and short wavelength sides [B9].

Al XIII

H I isoelectronic sequence

Ground state $1s\ ^2S_{1/2}$

Ionization energy 18 584 144 ± 2 cm^{-1} (2304.1410 ± 0.0007 eV)

The ionization energy and the 2*s* and 2*p* levels are from Mohr's calculations. The levels for $n \geq 3$ are from Erickson's calculations, adjusted to Mohr's value for the ionization energy. We included estimated small corrections to the QED contributions for the 3*s* and 4*s* levels. The calculated wavelengths have estimated uncertainties in the range from less than unity to a few units in the last decimal place.
