Received September 27, 1994; revised manuscript received October 5, 1994

Tables for form factors and anomalous dispersion are widely used in the UV, x-ray and γ -ray communities, and have existed for a considerable period of time. Much of the recent theoretical basis for these was contributed by Cromer, Mann and Liberman while much of the experimental data was synthesised by Henke *et al.* More recent developments in both areas have led to new and revised tables. These works have employed numerous simplifications compared to detailed relativistic S-matrix calculations; the latter do not lend themselves to convenient tabular application for the range of Z and energy of general interest. Conversely, the former tables appear to have large regions of limited validity throughout the range of Z and energies, and in particular have important limitations with regard to extrapolation to energies outside tabulated ranges.

In the present study, the primary interactions of x-rays with isolated atoms from $Z = 1$ (hydrogen) to $Z = 92$ (uranium) are described and computed within a self-consistent Dirac-Hartree-Fock framework. This has general application across the range of energy from 1–10 eV to 400–1000 keV, with limitations (described below) as the low- and high-energy extremes are approached. Tabulations are provided for the f_1 and f_2 components of the form factors, together with the photoelectric attenuation coefficient for the atom, μ , and the value for the K-shell, μ_K , as functions of energy and wavelength. Also provided are estimated correction factors as described in the text, conversion factors, and a simple estimate for the sum of the scattering contributions (from an isolated atom).

The method used herein is primarily theoretical and considers intermediate assumptions which limit the precision and applicability of previous theoretical tabulations. Particular concern involves the application of the dispersion relation to derive $\text{Re}(f)$ from photoelectric absorption cross-sections. The revised formulation presented here explicitly avoids most of the limitations of previous works. Revised formulae can lead to significant qualitative and quantitative improvement, particularly above 30–60 keV energies, near absorption edges, and at 0.03 keV to 3 keV energies. Recent experimental syntheses are often complementary to this approach. Examples are given where the revised theoretical tables are in better agreement with experiment than are those based on experimental syntheses. ©1995 American Institute of Physics and American Chemical Society.

Key words: anomalous dispersion; attenuation; $E = 1\text{--}10 \text{ eV}$ to $0.4\text{--}1.0 \text{ MeV}$; form factors; photoabsorption tabulation; scattering cross-sections; $Z = 1\text{--}92$.

1. Introduction and Importance of Form Factors

In the x-ray energy range covered here, the primary interactions of photons with atoms are photoabsorption and coherent (elastic) scattering. Inelastic (Compton) scattering

becomes dominant for all elements as the higher (γ -ray) energies are approached. For light elements, this transfer of dominance occurs at much lower energies (e.g. for hydrogen the inelastic component dominates above 3–5 keV). Additional nuclear scattering and absorption occurs at MeV energies, including pair production and Delbrück scattering from the nuclear field; and nuclear resonant processes (such as nuclear Thompson scattering).¹ For XUV photons at the lower end of the tabulated energy range, lattice phonon absorption, delocalized plasmon excitation, excitons and dipole resonances may appear.² Although these remain qualitatively identifiable as photon interactions with bound electrons, they are not associated with atomic orbitals or isolated atoms.

In the intermediate energy range, typically from 0.01–0.1 keV through to 80–800 keV, the interaction of the incident photon with the electrons — i.e. with the bound atomic orbitals — without production of secondary x-rays of reduced energy, is the dominant process. The photon is then either scattered without altering the internal energy of the atom, or it is absorbed. This absorption is usually into a single atomic orbital, with a consequent ejection of a photoelectron and production of a singly-ionized species.

Both photoabsorption and (Rayleigh) scattering are described by the structure factor F of the material in condensed or gas phase. In particular, diffracted intensity or coherent scattering is a complicated function of F , but for weak reflections is linear or quadratic in F . Equally, transmission through a bulk material is a complex function of F but local attenuation is a relatively simple function of the imaginary component of F .^{3–5} This is well known in the crystallographic community and is used extensively in the multilayer community at lower energies.^{6–8} The structure factor for a given reflection (denoted hkl from the Miller indices) is a sum over the atoms in the appropriate lattice (for a crystal) of the atomic form factors or the x-ray scattering factors f_j of the j^{th} atom:

$$F(hkl) = \sum_j f_j e^{-M_j} e^{2\pi i(hx_j + ky_j + lz_j)} \quad (1)$$

where thermal diffuse scattering is neglected, M_j is the thermal parameter for the given temperature, reflection and atom, and the location of the atom in the unit cell is given by (x_j, y_j, z_j) . For an isolated atom or a single elemental lattice, a scaled atomic form factor may therefore be substituted for the structure factor.

At grazing angles of incidence with solids, photons interact with the surface, and the photoabsorption and reflection processes may be given by Fresnel equations (while still dominated by electron orbital interaction and governed by the structure factor and form factors).⁹ If the atoms in a condensed system may be considered to scatter as dipoles (i.e. for low energies or small scattering angles) then the interaction of x-rays with matter may be described using optical constants such as the complex index of refraction n_r or the complex dielectric constant $\epsilon(E)$, which are related to the form factors by

$$n_r = n + ik = \sqrt{\epsilon} = 1 - \delta - i\beta = 1 - \frac{r_0}{2\pi} \lambda^2 \Sigma_j n_j f_j \quad (2)$$

where n_j is the atom number density and r_0 is the classical electron radius.

2. Form Factors and Standard Definitions

The real part of the atomic x-ray scattering factor is¹⁰

$$\text{Re}(f) = f_0 + f' + f_{\text{NT}}, \quad f' = f_1 + f_{\text{rel}} - Z \quad (3)$$

where $f'(E, Z) = f' + f_{\text{rel}}$ is composed of the non-relativistic anomalous dispersion f' and the relativistic correction factor f_{rel} . $f_0(q, Z)$ is the ‘normal’ coherent scattering factor as a function of momentum transfer $q = |\mathbf{K}_f - \mathbf{K}_i| = \frac{4\pi \sin \theta}{\lambda}$, the latter relation for elastic scattering through an angle 2θ .

$$f_0(q) = 4\pi \int_0^\infty \frac{\rho(r) \sin(qr) r^2 dr}{qr} \quad (4)$$

The dependences of f upon q and E may not be strictly separable as implied by the separation into f_0 and f' . Because of this, some authors define a modified form factor MFF (g)¹¹ or anomalous scattering factors (g' and g'').¹² The nuclear Thompson scattering (NT) is small and negative in phase relative to the electronic form factor ($f_0 + f'$), of magnitude $f_{\text{NT}} = -Z^2 m/M$, with small (negligible) energy and momentum dependence.^{13,14} The S-matrix channels of nuclear photoeffect (dipole resonance), pair-N, pair-e production and Delbrück scattering and other, smaller effects are typically neglected, providing upper limits in energy for the validity of these syntheses.

The imaginary part of the dispersion correction is simply linked to the photoeffect cross section $\mu_{\text{PE}}(E)$ (neglecting, or including, bound-bound cross-sections) at the photon energy E :

$$\text{Im}(f) = f''(E) = f_2(E) = \frac{E \mu_{\text{PE}}(E)}{2\hbar c r_e} \quad (5)$$

f_1 and f_2 are used in Refs. 7,15,16. The form factor f_1 is particularly useful in illustrating effects described here because it approximates $\text{Re}(f)$ in the forward scattering direction where $f_0 \approx Z$ and hence estimates the total scattering factor, placing the problems indicated on an absolute footing. It is also appropriate in typical experiments. The standard dispersion relation yields

$$f'(E, Z) = f'(\infty) - \frac{2}{\pi} P \int_0^\infty \frac{\epsilon' f''(\epsilon')}{(\hbar\omega)^2 - (\epsilon')^2} d\epsilon' \quad (6)$$

Here $E = \hbar\omega$ is the x-ray energy, ϵ' is the energy above the electron binding energy of the intermediate (bound or continuum) state, and P represents the principal value. Commonly the equation may be separated by orbital or by electron, with neglect of unoccupied bound states yielding

$$f'(E) = f'(\infty) - \frac{2}{\pi} P \int_0^\infty \frac{(\epsilon^+ - \epsilon_i) f''(\epsilon^+ - \epsilon_i)}{(\hbar\omega)^2 - (\epsilon^+ - \epsilon_i)^2} d\epsilon^+ \quad (7)$$

where $-\epsilon_i$ is the electron binding energy, and ϵ^+ is the (continuum) energy. The high-energy constant may be combined with relativistic correction factors to provide the separation into f_{rel} and f' as indicated above.

3. Available Tabulations and Basis of Current Formalism

This section discusses other available theoretical, experimental and synthesized tabulations for form factors and attenuation. The main sources for comparison are the theoretical development of Cromer, Mann and Liberman^{17–20}, the experimental-theoretical synthesis by Henke *et al.*⁷ and recent developments along both lines.^{21,15}

These works have employed numerous simplifications compared to detailed relativistic S-matrix calculations,¹² but the latter do not lend themselves to convenient tabular application for the range of Z and energy of general interest. Conversely, the earlier tables appear to have large regions of limited validity throughout the range of Z and energies, and in particular have limitations with regard to extrapolation to energies outside tabulated ranges. This is well known, and other tabulations of attenuation coefficients or form factors based on experiment or on alternate theoretical bases^{22,23} have met with partial success in some regimes, generally with corresponding areas of limitation elsewhere.

With the exception of high-order S-matrix calculations, the method of Refs. 17–20 may be expected to produce greatest theoretical precision and is perhaps predominant in the literature for the last decade. A number of intermediate theoretical and procedural assumptions limit the precision and applicability of this method. The current method, serving as a basis for the present tabulation, allows significant improvement both in the earlier tabulated range and in regions extrapolated with the formulae. A particular concern of the current author lies in suitable extrapolation to high and low energies, and interpolation to energies not covered by the $K\alpha$ values presented in the literature for these tables.

For this purpose a Fortran version of the code was gratefully received from S. Brennan²⁴ which contains the updates of Cromer and Liberman²⁰ in their source code presented in Ref. 18. In this method of Cromer and Liberman, relativistic SCF (self-consistent field) wavefunctions using the Kohn-Sham potential²⁵ and experimental energy levels²⁶ were used to compute partial photoelectric absorption coefficients ($\sigma(E)$) at ten or eleven selected energies, with the Brysk and Zerby program.²⁷ This introduces approximations regarding the potential and edge level derivation, but more significantly uses a model with no molecular or solid-state fine structure. Application of this code^{20,24} to near-edge regions of bound atoms is therefore limited by this procedure.

The development of Cromer and Liberman will be of prime consideration in the current discussion, together with the formulation for avoiding difficulties therein.²⁸ In the code of Ref. 20, separate partial cross-sections were calculated for most orbitals of each element in the range of $Z = 3–92$. However, some outer orbitals of higher Z elements were omitted or misplaced (with respect to their free-atom ordering or typical bonding patterns), which leads to inadequacies in these cases at lower energies. In the extreme case of Rb ($Z = 37$), 9 electrons and hence four sub-shells were omitted ($4s, 4p_{1,2}, 4p_{3,2}, 5s$) leading to unnecessary termination of the tables below 0.112 keV, and significant imprecision below 0.160–0.200 keV, whereas formal results could have been

given down to 0.004 keV. Most elements include all edges down to about 0.050 keV, and light elements (to Ca) generally include all orbitals.

For each orbital, five cross-sections $\sigma(E)$ covered energies of 5–23 keV¹⁸ or 1–80 keV,²⁴ for interpolation and determination of $f''(E)$ (the imaginary, absorptive component of the scattering factor). If the binding energy lay in the range $1 \text{ keV} < -\epsilon_1 < 70 \text{ keV}$, an additional point applied to $E = -1.001\epsilon_1$. An additional five values covered the above-edge range (with energies set for 5-point Gauss-Legendre integration). This second group of 5 points applied to the integral of $f''(E)$ to give $f'(E)$: the locations of E and the form of the integral chosen depends on whether $-\epsilon_1 < 1 \text{ keV}, -\epsilon_1 > 70 \text{ keV}$, or $-\epsilon_1$ is of intermediate energy.

4. Basic Transform Equations

Appropriate formulae based on Eq. (7) should give a small and smooth integral over the range of the variable of integration, with the dominant term given by analytic form. The situation may be illustrated by considering the above-edge case, given by Eq. (27) of Ref. 17:

$$f^+ = \left(\int_0^\infty \frac{\sigma(\epsilon^* - \epsilon_1)(\epsilon^* - \epsilon_1)^2 - \sigma(\hbar\omega)(\hbar\omega)^2}{(\hbar\omega)^2 - (\epsilon^* - \epsilon_1)^2} d\epsilon^* + P \int_0^\infty \frac{\sigma(\hbar\omega)(\hbar\omega)^2}{(\hbar\omega)^2 - (\epsilon^* - \epsilon_1)^2} d\epsilon^* \right) / 2\pi^2\alpha \quad (8)$$

with α the fine structure constant and σ in atomic units (au). Gauss-Legendre integration points are fixed by the order of the integration, but corresponding energies may be adjusted to optimize the precision for a particular photon energy by scaling (contracting or expanding) the integrating variable, following (but in contrast to) Eq. (29) of Ref. 17 (for Eq. (8)):

$$x = \begin{cases} \frac{|\epsilon_1|}{\epsilon^* - \epsilon_1}, & \hbar\omega = 2|\epsilon_1| \\ \left[\frac{|\epsilon_1|}{\epsilon^* - \epsilon_1} \right]^2, & \hbar\omega \leq \sqrt{2} |\epsilon_1| \\ \left[\frac{|\epsilon_1|}{\epsilon^* - \epsilon_1} \right]^{1/2}, & \hbar\omega \gg 2|\epsilon_1| \end{cases} \quad (9)$$

Note that $\epsilon^* > 0$ and $-\epsilon_1 > 0$ and the integration limits are transformed from $(0, \infty)$ to $(1, 0)$, while in the first case $\sigma(\epsilon^* - \epsilon_1)$ becomes $\sigma(-\epsilon_1/x)$. By symmetry, this yields a well-defined integral which properly ranges from 0 to 1.

Following the same formalism as in 17–20, improved if not fully optimized relations for f^+ may then be given as

$$f^+ = \frac{1}{2\pi^2\alpha} \int_0^1 \sigma_i d\epsilon^* - \frac{\hbar\omega}{4\pi^2\alpha} \sigma(\hbar\omega) \ln\left(\frac{\hbar\omega - \epsilon_1}{\hbar\omega + \epsilon_1}\right), \quad |\epsilon_1| < \hbar\omega; \quad (10)$$

$$\sigma_i = \begin{cases} \sigma_2, & \hbar\omega \gg 2|\epsilon_i| \\ \sigma_0, & \hbar\omega = 2|\epsilon_i| \\ \sigma_4, & \hbar\omega \leq \sqrt{2}|\epsilon_i|; \end{cases} \quad (11)$$

$$\sigma_2 = \begin{cases} -2\sigma(|\epsilon_i|/x^2)\epsilon_i/x^3, & |\epsilon_i|/x^2 = \hbar\omega \\ 2\left(\frac{\sigma(|\epsilon_i|/x^2)\epsilon_i^3/x^4 - \epsilon_i(\hbar\omega)^2 \sigma(\hbar\omega)}{x^3(\hbar\omega)^2 - \epsilon_i^2/x}\right), & \text{otherwise}; \end{cases} \quad (12)$$

$$\sigma_0 = \begin{cases} -\sigma(|\epsilon_i|/x)\epsilon_i/x^2, & |\epsilon_i|/x = \hbar\omega \\ \left(\frac{\sigma(|\epsilon_i|/x)\epsilon_i^3/x^2 - \epsilon_i(\hbar\omega)^2 \sigma(\hbar\omega)}{x^2(\hbar\omega)^2 - \epsilon_i^2}\right) & \text{otherwise}; \end{cases} \quad (13)$$

$$\sigma_4 = \begin{cases} -0.5\sigma(|\epsilon_i|/x^{1/2})\epsilon_i/x, & |\epsilon_i|/x^{1/2} = \hbar\omega \\ 0.5\left(\frac{\sigma(|\epsilon_i|/x^{1/2})\epsilon_i^3/x - \epsilon_i(\hbar\omega)^2 \sigma(\hbar\omega)}{\sqrt{x}(\hbar\omega)^2 - \epsilon_i^2}\right), & \text{otherwise}; \end{cases} \quad (14)$$

for $\hbar\omega > |\epsilon_i|$ (above the edge). At the edge, use $\hbar(\omega + \delta\omega)$ to avoid the computational singularity. Below the edge ($|\epsilon_i| > \hbar\omega$),

$$f^+ = \frac{1}{2\pi^2\alpha} \int_0^1 \sigma_i \, dx + \frac{\epsilon_i^2 \sigma(|\epsilon_i|)}{4\pi^2\alpha\hbar\omega} \ln\left(\frac{|\epsilon_i| - \hbar\omega}{|\epsilon_i| + \hbar\omega}\right); \quad (15)$$

$$\sigma_i = \begin{cases} \sigma_3, & \hbar\omega \approx 2|\epsilon_i| \\ \sigma_5, & \hbar\omega \ll 2|\epsilon_i|; \end{cases} \quad (16)$$

$$\sigma_3 = c_i^3 \left(\frac{\sigma(|\epsilon_i|/x)/x^2 - \sigma(|\epsilon_i|)}{(x\hbar\omega)^2 - \epsilon_i^2} \right); \quad (17)$$

$$\sigma_5 = 0.5\epsilon_i^3 \left(\frac{\sigma(|\epsilon_i|/x^{1/2})/x - \sigma(|\epsilon_i|)}{\sqrt{x}(\hbar\omega)^2 - \epsilon_i^2} \right); \quad (18)$$

where, again, $\sigma(|\epsilon_i|)$ is given by $\sigma(|\epsilon_i|(1+\delta))$ to arbitrary precision. The second terms of Eqs. (10) and (15) are always negative, while the first term in Eq. (10) is positive and the first term in Eq. (15) is negative. Use of (these) appropriate functions can lead to problems where integration points would lie beyond the database (11 data points per orbital). In such cases, the above-edge or below-edge behavior should be retained, but the choice of form may be modified appropriately to match the data and to optimize precision. The effects of this formalism and these specific modifications, compared to the earlier results, may be seen generally near edges, at energies below 2 keV or above 70 keV, but also at intermediate energies.

5. Avoidance of Singularities in $f'(E)$ Above Edges

The functional forms of the integral of f'' as indicated in Refs. 17–20 are formally continuous above each edge but include singularities in both numerator and denominator (which cancel). Consequently, the code of Cromer and

Liberman^{17–20} yields divide-by-zero errors for $Z = 18$ (argon, 1.28 keV) and elsewhere at energies for $Z > 2$ corresponding to cancellations (5 per orbital).

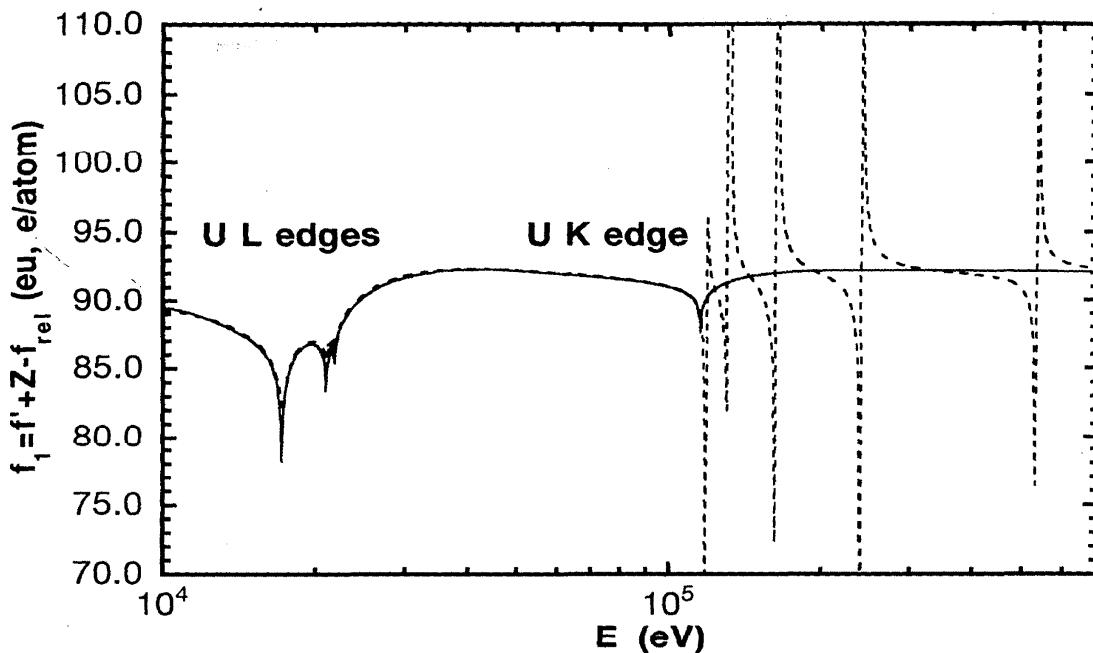

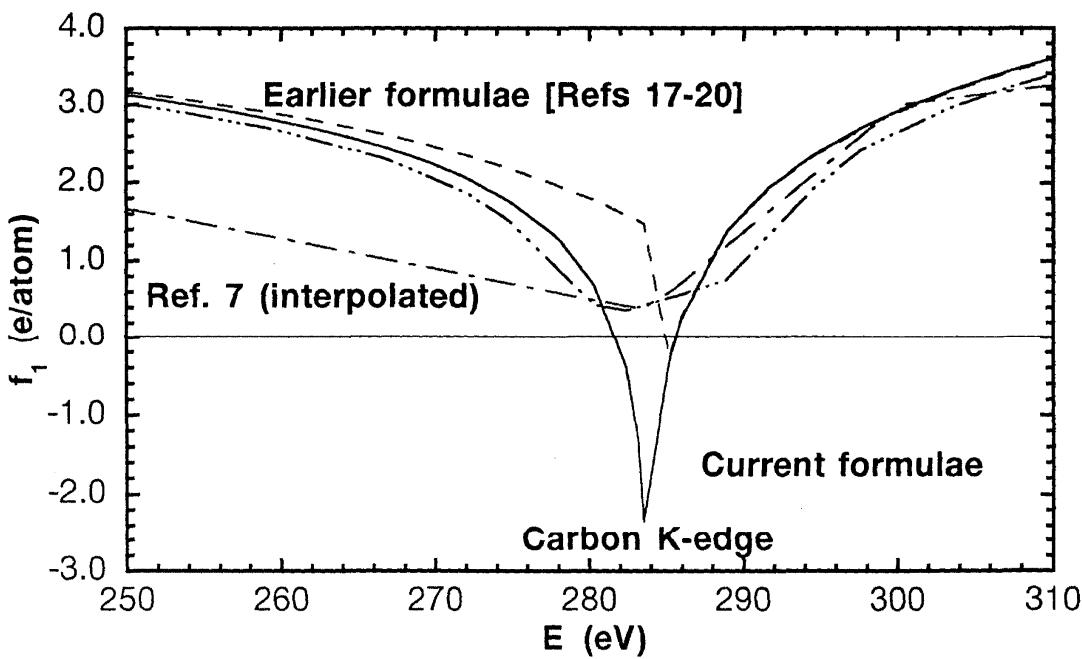

The functional forms indicated^{17–20} were otherwise appropriate and valid in the 5 keV–50 keV range. This was the main concern of the authors, but extension beyond this range in either direction requires reevaluation of the construction. In particular, the forms pertain to $E \gg -\epsilon_i$, $E = -\epsilon_i$, and $E \ll -\epsilon_i$ and not to $-\epsilon_i < 1$ keV, $-\epsilon_i > 70$ keV. Further, that for $-\epsilon_i > 70$ keV omitted a correction which is increasingly important as E approaches $-\epsilon_i$. The nature and magnitude of this latter problem is depicted in Fig. 1 for uranium. The apparent ‘edge’ is displaced and offset by several keV with five discontinuities, and at 500 keV (four times the edge energy) the error is of the same magnitude as Z . This energy range is much higher than that of Refs. 15, 17–21. In these figures and in the text, the current formulation avoids or overcomes all problems discussed, as far as is possible within the prescriptions provided. The use of f_1 as the plotting variable follows the standard of Refs. 7, 16 but more importantly places the effects on an approximate absolute footing for the real component of the atomic scattering factor in the forward direction.

6. Avoidance of Imprecision in $f'(E)$ Below and Near Edges

Corrections for below-edge behavior applied to the second (intermediate energy) form in Ref. 18 should also be applied to the other two forms as detailed in section 4. Near to but above edges where $-\epsilon_i < 1$ keV, the integration is improved by using a form similar to the ‘higher-energy’ forms rather than that previously indicated, which was optimum only for $E \gg -\epsilon_i$. Well below edges where $-\epsilon_i > 1$ keV, the integration is improved by using a form similar to the ‘high-energy’ form rather than that previously indicated, which was optimum for $E \approx -\epsilon_i$. In any of these regions where the functional forms are inappropriate, some improvement in precision can often be gained by using 10-point or higher order Gauss-Legendre integration. This represents improved precision of the integration using a less optimum integral transformation.

Previous below-edge errors are illustrated for the K edge of carbon in Fig. 2. The edge was apparently displaced and asymmetric (typically with a spurious value for the edge itself) as opposed to the revised form (‘o’ versus ‘+’ in figure). There were also significant errors in the earlier prescription 12% below the edge. This also occurs with similar magnitude (4 e/atom) for the L-edges of uranium at 17–22 keV in Fig. 1. These errors occur at energies well within the range of crystallographic investigation and concern, and are not restricted to regimes of specialized anomalous or other diffraction experiments.

The theoretical-experimental synthesis of Ref. 16 (triangles) is in reasonable agreement with the current revised results well away from the edge, with the exception that aliasing is introduced due to the finite logarithmic grid on which linear interpolation is carried out. This means that the transform is calculated appropriately from the given absorption coefficients to yield f_1 values for specific energies, but

FIG. 1. Form factor f_1 for uranium near K- and L-edges indicating above-edge errors following references 17-20. (Solid line indicates current formulation.)FIG. 2. Form factor f_1 for carbon near K edge indicating asymmetry and discontinuity produced by earlier formulae (dashed line, Refs 17-20), and inadequacy of synthesised data (dot-dash, Ref. 7; ... , Ref. 16), versus the current formulation (solid line).

subsequent interpolation between these points smooths out any finer structure, in addition to generating an interpolation error even in the absence of structure. The earlier synthesis⁷ contains a much coarser grid, so direct comparison of the two primarily indicates interpolation limitations. The relativistic correction factor is only about 0.004 (e/atom or eu in crystallographic notation) and makes negligible contribution to the results (whatever form is postulated for the correction), while $f_0 \approx Z - 0.04$ eu, and does not affect the comparison. Hence a typical experiment in this regime with graphite or other elemental carbon should relate to a real component of the atomic scattering factor given to high precision by f_1 . The current revised formalism yields a width (below zero) of 4.6 eV and a mean f_1 of circa -0.9 eu over this region, with $f_1 = -2.4$ eu at 0.24 eV from the edge, or $f_1 = -4.0$ eu at 0.07 eV from the edge (or about the edge width).

The independent particle approximation common to all theories discussed herein *should* yield the revised smooth, symmetric form, but the formalism may be expected to fail near edges or at low energies, where molecular or collective behavior may occur. However, the revised result is in good agreement with Cherenkov radiation studies on the carbon K edge,²⁹ which have derived widths of 5 eV and a mean susceptibility $\chi' = 0.0016$ or $f_1 \approx -0.82$ eu, and minima of -2.0 eu > $f_{1,\min} \approx -5.1$ eu.

Conversely, aliased profiles¹⁶ give minima of 0.3 eu > $f_{1,\min} \approx -1.3$ eu, non-aliased transforms of a simple edge structure³⁰ yield $f_{1,\min}$ from -5.3 eu to $-\infty$ eu and a width of order 5 eV, while other recent experimental f'' measurements yielded a width of around 14 eV and $f_{1,\min} \approx -1.2$ eu after integration.³¹ All are in disagreement with the Cherenkov studies. In this respect, the importance of *direct* measurements of the scattering factor (anomalous or atomic) cannot be overestimated. Finally, the result of Ref. 21 which might be expected to include contributing collective behavior, appears to give a shift and singularity in the structure.¹⁵

7. Integration Precision Requirements

Several integration procedures were investigated and compared. Five-point Gauss-Legendre integration yields convergence to 5% in many but not all cases where the form is appropriate. In some cases (near edges, particularly with functions not corrected for above or below-edge behavior) a 30-point integration was found inadequate.²⁰ Five-point integration appears adequate for low Z to about 0.01 eu in most regions, while yielding errors of 0.1 eu for silicon near edges, where 10-point and 16-point results appear identical. This error rises to above 1 eu for silver ($Z = 47$) and 5 eu for uranium (Fig. 3), with shifts of 0.3 eu and 1.3 eu, respectively, even midway between edges. The difference between 10-point and 16-point integration is also significant at the 0.15 eu level for $Z = 92$, and is fairly uniform for all energies. The figure indicates major integration and interpolation error in the unrevised formalism^{17-20,24} of magnitude 1-4 eu across the medium energy range of 4-6 keV. This may also be compared to Refs. 15, 16 (including a partial f_{rel} correction of perhaps -1.5 eu), apparently erroneous by up to 5 eu. Although uranium is perhaps an extreme case, this situation is reflected

throughout the medium and higher range of Z . The 16-point integration is therefore used and commended, covering a much larger energy regime with higher precision.

8. Choice of Interpolation Formalism

The 'convergence' with improved integration precision is partially due to inadequacy of interpolation methods rather than convergence to the value predicted by the independent particle approximation. The code of Cromer and Liberman¹⁸ 'interpolates' over $\ln(f'')$ using a quadratic least-squares fit. This smooths precision-dependent noise but also obscures significant local or higher-order structure. The 5 energies used are not well spaced for interpolation to other f'' values, whether for integration or otherwise. Ref. 24 assumes a cubic form for the $\ln(f'') - \ln E$ functional relation and uses the Aitken interpolation method; this combination generates non-monotonic and spurious f'' values near to or far above the edge. Reference 22 used a linear interpolation on log-log scales for $E < 1$ keV and noted significant errors for cubic spline interpolation at higher energies (for $Z = 24, 42, 44, 67-69, 75, 76, 85$).

Rational function interpolation is well able to model simple cubic terms (on the log-log scale) but is quite inappropriate for extended or oscillating structure. The latter would commonly produce a pole in the resulting fit near to the real plane and therefore generate large errors. Most investigators have (therefore) relied on polynomial interpolation on the log-log scale.

At energies far above the edge, the form $f''(E) = f_2(E)$ is expected to become approximately cubic, or linear in $\ln f''(\ln E)$. With the photoabsorption data of Refs. 17-20, higher accuracy would follow from correct evaluation of higher order terms but data points are unequally spaced, so divergences easily follow extrapolation or interpolation. This may be limited by extrapolating or interpolating at either end of the energy range with a linear log-log form, while allowing intermediate values to be affected by higher order contributions. Interpolating functions may further be limited to symmetric forms about the region interpolated (i.e. to linear, cubic or quintic log-log interpolation using $n = 2, 4$, or 6 data points). Given a sufficiently fine grid, interpolation becomes insensitive to the form used. However, the database discussed herein lacks such a fine grid, drawing attention to the appropriate forms of interpolation. This is illustrated in Fig. 4 for medium energy attenuation by uranium, where the asterisk notes the reduction to a linear log-log form for extrapolation, thus avoiding unnecessary oscillations. Even so, the curves do not converge or maintain a constant ordering, and differ by up to 4 e/atom (eu) or 15% in this range, without the correct form being immediately apparent.

The problem repeats itself for lower energies (less than 9 keV) and also for higher energies (above 30 keV) for most elements. and effects of this problem upon f' are often as large. Examples from other elements and regimes allow additional general rules to emerge: Linear log-log interpolation fails near edges (even within the independent particle approximation) where higher order terms are often significant and necessary. Conversely, these are generally absent far above

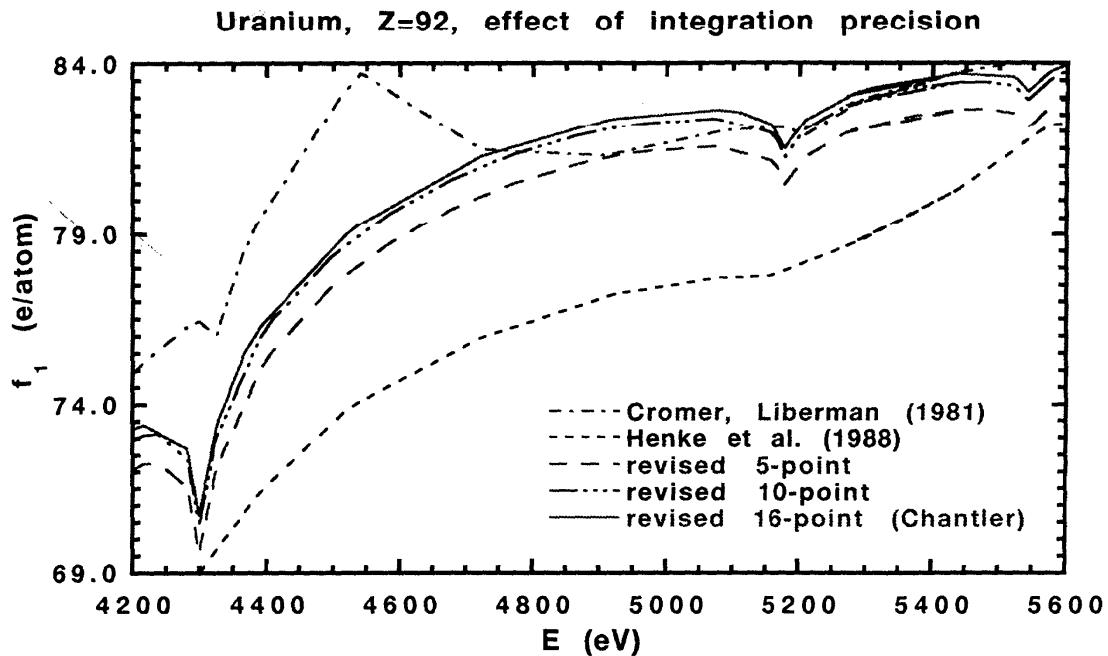

FIG. 3. Form factor f_1 for uranium $M_I - M_{III}$ edges showing importance of higher precision integration and the use of the current method versus earlier methods¹⁷⁻²⁰ and synthesised data.^{15, 16}

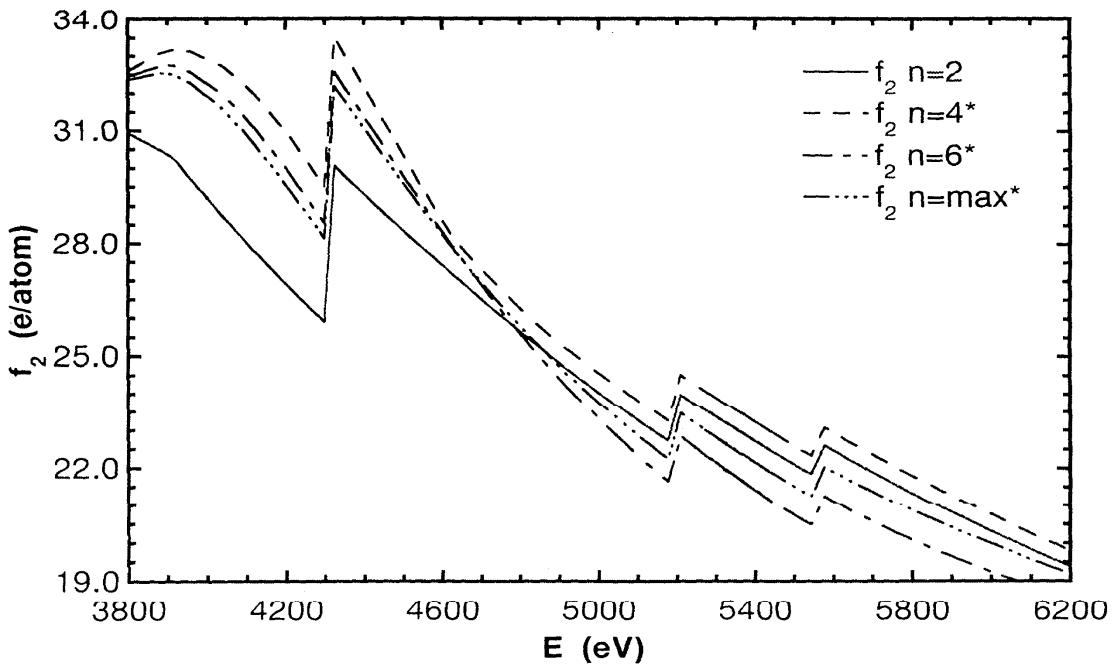

FIG. 4. Form factor $f_2 = f''(E)$ for uranium near M_I and M_{II} edges showing large variation between interpolation procedures. n is the number of points in the interpolation, so $n=2$ refers to the linear log-log form.

edges and use of them can introduce spurious oscillations from their contribution in the near-edge region. The relation relatively near edges is often cubic in $\ln f'(\ln E)$ so that a transition from this to the linear form may be accomplished at intermediate energies above each edge. The location of the transition is dependent on the element and edge, and appears (in the current database) to lie between a factor of 1.5 and 4 above the edge.

This prescription is not rigid, but variation between possible alternatives is estimated at (usually) below 1–2%. This allows meaningful comparison of models with experiment, which would otherwise be difficult or dubious. Figure 5 returns to uranium at intermediate energies, again emphasizing the potential utility of the current formalism as opposed to earlier forms and synthesised data. Here experiment^{32,33} strongly supports the current formalism and interpolation procedure.

Even at these energies, the contribution of coherent scattering σ_{coh} to the total attenuation coefficient $\mu_{\text{TOT}} = \mu_{\text{PE}} + \sigma_{\text{coh}} + \sigma_{\text{inc}}$ is significant and should not be neglected in these comparisons. (The high-precision experimental data^{32,33} necessarily measures the total attenuation coefficient, and not the photoeffect cross-section (σ or μ_{PE}) in isolation.) The estimate of scattering follows Refs. 34, 35 and may only be accurate at the 10% level, dependent on the experimental arrangement. Neglect of this contribution is still unable to bring Ref. 24 or Ref. 16 into good agreement with experiment in this region.

Elsewhere, however, the local structure allows no simple set of polynomial interpolations (for a given orbital). Typically at low energies and L_1 , M_1 and M_{1v}/M_{1u} edges, the local structure is real but subsequent polynomial extension yields large oscillations well away from the structure. Early truncation to linear forms yields discontinuities in f_2 or its derivative. Scaling any deviations above or below the interpolated points by a constant factor (e.g. 0.5) or a decreasing smooth function can serve to smoothly suppress invalid oscillations. Similar capping or scaling of large deviations from the linear interpolation can also suppress oscillations, but it is difficult to have a uniform and general method which avoids introducing f_1 structure from discontinuities in the derivative.

Any such effects are likely to produce significant features (cusps, peaks or derivative discontinuities) in f_1 . The most significant effects of this sort are found in the K-edge of Na and Mg, L-edges for $Z = 4$ –14, around the L_1 edge for $Z = 30$ –36, M-edges of $Z = 13$ –33, around the M_1 edge for $Z = 61$ –68, and N-edges for $Z = 55$ –65. Problems with cubic spline interpolation were noted earlier.

Extrapolation near the edge is well defined using a linear log-log form matching to the derivative of the following polynomial. Particular regions were interpolated using the polynomial forms, but with a smoothly increasing weighting for the linear solution across the transition region (as opposed to the above alternatives). This smooths the approach to the high-energy linear log-log regime without discontinuity of function or derivative, while remaining uniform and general in application.

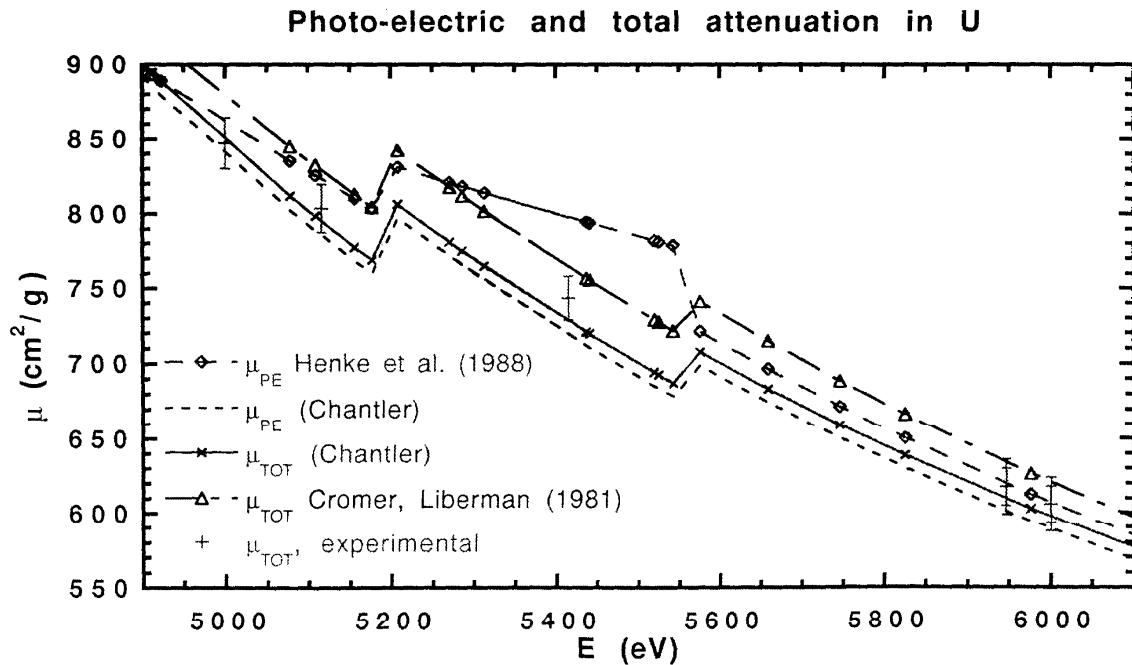

FIG. 5. Photoelectric absorption coefficient for uranium near M_{1v} and M_{1u} edges showing offset of interpolation procedures and agreement of experiment^{32,33} with current computation versus synthesised data¹⁸ and earlier procedures.²⁴

9. Results for Hydrogen and Helium

Hydrogen and helium serve as another example or extension since the general Cromer-Liberman approach did not apply to these two elements.^{17–20} The form is however simple, adapted in part from McMaster *et al.*³⁵ The main difference between the (plotted) synthesis of Henke *et al.*^{15,16} and the current form lies in the range and precision of the computation, the location of edge energies, the effective number of electrons assumed, and the interaction with scattering data. In all these respects, the current tabulation appears superior as a statement of atomic form factors.

However, use of atomic form factors in compounds or solids, particularly for hydrogen, involves significant shifts and potential structure not contained in these plots or tables. These chemical shifts and bonding redistributions serve as a caveat on use of the lower energy data (unless gaseous atomic hydrogen is used). Nonetheless, the data is able to represent a good approximation in general cases.

10. How to Use These Tables

These tabulations provide f_1 and f_2 form factors for all elements up to $Z = 92$ from 0.001–0.01 keV to 1000 keV. This exceeds the range for normal x-ray diffraction and crystallography studies but allows limitations and specialized experiments to be investigated with reference to updated and corrected theory. It also allows a sufficiently fine grid with accurate atomic edge structure to allow such experiments as DAFS (diffraction anomalous fine structure) to investigate fine structure and spatial distribution of atoms and electrons within materials.³⁶ Multilayer diffraction experiments may be pursued at lower energies in an analogous manner.

In these cases values for f_1 and f_2 should be extracted from the tables for the given element(s) and energies required. Linear interpolation of f_1 should be adequate, while linear log-log interpolation of f_2 should be adequate on this scale, if required. Equation (3) should then be used to obtain f' using the negative value of f_{rel} as included at the top of each table for each element. For comparison to old data or computations, the value corresponding to reference 6, denoted H82, should be used (following Cromer and Liberman but omitting the Jensen energy-dependent correction).^{17–20,37} More recent work has suggested not only that the Jensen term should be omitted but also that the appropriate relativistic correction is 3/5ths of the Cromer-Liberman value.^{38,39} This latter value is denoted 3/5CI at the top of each table for each element. Likewise, the nuclear Thompson term (also negative with respect to the atomic phase) is provided at the top of each table for each element.

For comparisons to other results in the forward scattering limit where the momentum transfer $q = 0$, the value of $f_0 = Z$ may be used and the real and imaginary components of f are then fully defined. For large scattering angles it is necessary to use a more appropriate value of f_0 , as may be gained from Refs. 40–41. Then the composition and arrangement of the material may be used as indicated in the introduction to provide structure factors, refractive indices, and Fresnel coefficients, together with scattered, diffracted or transmitted intensities.

For filters or filter materials, the photoelectric attenuation coefficient is provided in order to compare to appropriate experiments or to allow for objects in a beam-line. The conversion to this from f_2 in appropriate units is provided at the top of the table. Use of barns/atom is also common, and the conversion factor for this is also provided. Often this column is not measured, and only the total observed attenuation coefficient $\mu_{\text{TOT}} = \mu_{\text{PE}} + \sigma_{\text{coh}} + \sigma_{\text{inc}}$ is observed. These latter two coefficients are angle-dependent and may in part be determined from appropriate structure factors for a given crystal orientation. However a column is provided for the sum of these two latter coefficients in an average-over-angles for an atomic scatterer.^{34,35} These references should be consulted for details concerning the approximation involved, although the column in the current tabulation is a new computation of the sum. The main assumption is that Bragg-Laue peaks and troughs are avoided, or that the material is randomly oriented and preferably mosaic. If this is not true, it may be necessary to compute the dynamically diffracted intensities from the structure factor rather than rely on the approximation. Further comments are provided in the next section. However, simply summing these two columns allows the comparison of theory to experimental attenuation data.

The column providing the photoabsorption coefficient for the K-shell only is included for two purposes. The first is that at high energies this is the dominant contribution to the total photoabsorption, and provides a guide for the local energy dependence of the cross-section. It serves as an illustration of the isolation of individual orbital cross-sections, particularly for higher energies.

The isolated K-shell cross-section is also important for experimental diagnostics and corrections. In particular, fluorescence yields from atoms are negligible for almost all orbitals except the K-shell, when compared to Auger and Coster-Kronig transitions. However, the fluorescence yield fraction for the K-shell is large, so the dependence of the cross-section upon energy is equally important. The qualitative result in an experimental ion chamber is significant — in these processes, a likely result is that the fluorescent x-ray shall escape from the ion chamber without conversion to (detectable) ion pairs. A more detailed discussion of this is provided elsewhere.⁴²

The plots provide additional data not contained in the tables. This includes a plot of the K-shell contribution to the imaginary component of the form factor f_2 . This is related, as discussed, to the K-shell contribution to the photoabsorption cross-section. The enhanced energy range provides an indication of the appropriate extrapolation to higher energies. It also provides the atomic orbital computation of the lower energy behavior, despite increasing imprecision as the energy falls below 0.010 keV.

The plots also provide comparison to the results of Henke *et al.*^{15,16} This is considered by the author to be the most useful and convenient publication available for comparison. It indicates limitations regarding restricted ranges and tabulation steps, shows good agreement over much of the energy range for many elements, and indicates regions of divergence, difficulty or concern. Some of these concerns have been addressed directly in this paper, while others are left to the

reader. In many cases the best naïve statement of uncertainty in either computation arises from the divergence between the two. This may relate to local structure, absolute values, or global structure. An alternate error estimate is provided in the following section.

For less common use, the edge energies used are provided at the top of each table so that criticism (or experimental investigation) may indicate a shift of the local energy scale which *may* be appropriate in a specific material or experiment. This is not encouraged or recommended; nonetheless, it is provided as a statement of the assumptions and basis of the computation.

11. Limitations of the Current Tabulation

There are many regimes of Z and E where most recent tabulations are in agreement at the 5% level, particularly well away from edges in the 5–40 keV range, in lower Z elements, and in f'' or μ_{PE} tabulations. Intermediate regimes often impair comparison of tabulations with experiment as uncertainty in f_0 , f'' , f_{rel} , incoherent scattering and integration may all lie at the same level.

There are also regions in some elements where alternate tabulations are clearly superior to Refs. 17–20, 24 and the current formulation. Delays of onset of photoabsorption for 20 eV (3%) above the edge, and peak amplification by factors of two for another 20–40 eV for monatomic gases (e.g.) also occur, not predicted within hydrogen-like calculations and

those assuming plane wave continuum states.⁴³ Tabulations based on the local density approximation (LDA) or on experimental-theoretical syntheses^{15,16,21,30} have potential advantages particularly in low energy regimes such as Fig. 6 where collective valence effects or dipole resonances lead to significant departures from the independent particle approximation. The omission of some outer orbitals, mentioned earlier, accentuates this problem in some medium- Z elements in this same energy range (i.e. up to 0.1 keV or so). In such low energy regimes, seminal and early experimental work and local transforms can still play an important role in revealing additional structure or correcting model-based assumptions.⁴⁴

Often the ‘best’ tabulation in these cases may be fairly inaccurate, due to intrinsic limitations or additional contributions from exciton resonances or band structure. In the example of Fig. 6, early syntheses⁷ differ substantially from later equivalents^{15,16} and references^{17–20, 24} differ markedly from that of the current calculations. Above or below the range of Fig. 6, predictions of the real and imaginary components of atomic form factors from Ref. 16 and herein often agree fairly closely. Discrepancies of an order of magnitude appear in the plotted range. The predictions of Ref. 16 for f_1 and f_2 (that is, the estimated total form factors), though probably the best available elsewhere for most of this region, are limited by the input data, theory and synthesis to be accurate to not much better than a factor of two. This limitation of general tabulations is also true in the near vicinity of edges affected by valence or molecular structure.

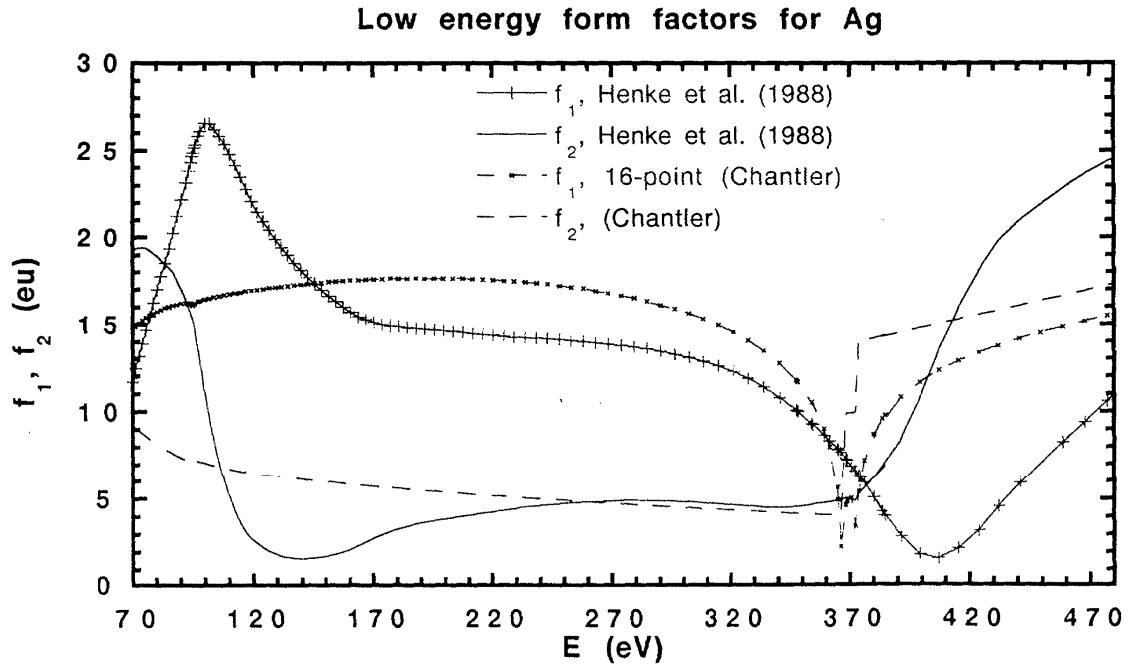

FIG. 6. Example of region for Ag where current method fails to improve over theoretical-experimental synthesis due to collective behaviour. Differences of an order of magnitude in f_1 relate to corresponding differences in $f'' \approx f_2$, from smoothed delayed edges and a dipole resonance. Both predictions differ from earlier synthesis and theory by factors of two, and primarily differ from one another in the vicinity of edges. Edges at higher energies appear largely unaffected by this collective behaviour.

Conversely, syntheses^{7,15,16} tend to diverge from experiment and theory where numerous edges occur or where data do not give detailed variation between and at edges. Divergence can be due to smoothing of edge structure, weighting of experimental data, or Z-interpolation. These are regions of particular usefulness of the current tabulation.

High-energy and high-momentum transfer limitations follow in part from dominance of nuclear resonance and pair-production channels. Each of these attenuation and scattering processes are ideally independent,³⁸ or add together with a well-defined phase (as with the nuclear Thompson term in section 2).¹² General neglect of other contributions does not intrinsically invalidate computations of atomic form factors, but it seriously limits their usefulness and applicability, and the precision to which measurements of these quantities may be made at these high-energy, high-momentum transfer regimes. Hubbell *et al.*⁴⁰ include corrections for radiative and double-Compton contributions to incoherent cross-sections, reaching 1% at 100 MeV energies. Nuclear-field pair production κ_n arises at $2m_e c^2 = 1.022$ MeV and becomes dominant around 10 MeV. Electron-field pair production ('triplet production') begins at 2.044 MeV and contributes above this energy at the 1% level for high Z elements but up to 10% for fluorine and 50% for H (or $1/(1+Z)$). Nuclear photoabsorption consists of one (or a few) peaks (giant resonances) between 10–24 MeV of width 3–9 MeV, contributing up to 10% of the total cross-section in this region. Elastic processes include high energy Delbrück and dipole resonance scattering in addition to Rayleigh and nuclear Thompson contributions mentioned above.

Below these high-energy limits but above 10–300 keV (dependent on Z), incoherent scattering forms the dominant attenuation process, and may be given to 1–2% by integration of the Klein-Nishina formula. Interference between this channel and photoabsorption can affect total cross-sections and form factors at the 5% level.

In the region 10–40 keV elastic scattering may exceed photoabsorption cross-sections (especially at Bragg peaks). This is of prime importance for estimates of total attenuation cross-sections μ_{TOT} or for attempts to compare f'' to experimental cross-sections, and is complicated by the coherence of scattering between adjacent atoms, leading to TDS (thermal diffuse scattering) and Rayleigh single-atom estimates in addition to accurate derivations from the form factor f_1 and diffraction formulae. Of course, a prime purpose of the current discussion has been to generate accurate form factors which can then be used to determine total attenuation (i.e. photoabsorption plus diffraction) for a given orientation of a sample to high precision. They can then be compared to experimental values.

Simple available and tabulated estimates of orientation-averaged scattering can err by orders of magnitude in special arrangements, though they are usually more accurate than this. The simple forms commonly used for such scattering assume that each atom is isolated, so integration neglects crystal orientations leading to Bragg-Laue peaks or hollows. This Rayleigh scattering may be replaced by a TDS cross-section if the crystal orientation is arranged to avoid Bragg-Laue peaks.⁴⁵

12. Other Current Concerns

Most of this description has been concerned with problems of f' or f_1 and f'' or f_2 . Difficulties inherent in the form factor formalism as opposed to the Modified Form Factor formalism or general S-matrix formalisms are discussed elsewhere.^{46,47} Use of Modified Form Factors is of value at or above MeV energies for various angles, where the separability of f_0 and f_1 becomes questionable.¹⁰ Sum rules have been discussed and investigated, particularly at relatively low energies,^{48,49} and may be more generally applied to theoretical or experimental data. Comparisons of form factor predictions to others or to experiment without allowance for the issues raised in this paper will endanger the validity of conclusions drawn.

One of the major differences between these classes of theory, and in particular between RDP, RMP^{38,39} and S-matrix methods¹² relate not to f_1 or f_2 per se, but relate to the relativistic correction factor f_{rel} . This contribution indicates the correction for the high-frequency limit. For uranium at low energies f_{rel} is of order -2.5 e/atom,^{17–20} -1.5 e/atom,^{38,39} or -1.2 e/atom.^{12,39} The differences between these theories are large, with a range at the 1 e/atom level and an uncertainty quoted as ± 0.36 e/atom.³⁹ Equally, for calcium ($Z = 20$), quoted values vary from -0.06 eu to -0.036 eu to -0.034 eu with, again, a quoted uncertainty of ± 0.009 eu.³⁹ These are important and significant differences (particularly for medium and heavy elements), although it should be clear that any comparison of theories or experiments is difficult without correcting for the effects discussed herein with their associated many-electron errors. Issues regarding the forms for f_{rel} demand that input values for f_1 be calculated to better precision than the uncertainty in the relativistic component. Errors of the preceding sections or of integration or interpolation precision at this level are unnecessary and obscure comparison of different models with experiment.

The integration method adopted and discussed herein makes direct use of the separation of orbitals and the assumption that the orbital absorption coefficient is exactly zero below the edge. Correlation between orbitals, excited bound states, level widths and resonance phenomena may require alternate transforms based on $\hbar\omega = (0,\infty)$ to $(0,1)$ intervals. This general issue was addressed by Cromer and Liberman¹⁷ and has been addressed more recently by Wang and Pratt.⁵⁰ The presence of multiple edges and near-singularities creates difficulty for most standard integration methods. For comparison of theory to experiment, direct measurement of $\text{Re}(f)$ is required, but the current revised theoretical calculation has an advantage over methods based on limited ranges of experimental or synthesized attenuation coefficients, in avoiding smoothing and other problems near edges.

A secondary difficulty, so far as published results are concerned, relates to tabulations often being restricted to a small set of $K\alpha$ lines, or to other discrete sets of energies which fail to reveal major variation of structure with energy.

13. Summary and Typical Uncertainties

The modifications described herein lead to significant qualitative and quantitative improvement, particularly above

30–60 keV energies, near absorption edges, or at 0.03 keV to 5 keV energies. With limitations, the current scheme is able to extend to energies below 0.01 keV. More confidently, it also covers the region above 30 keV towards MeV energies, unlike most tabulations. The current tabulation is complementary to recent experimental syntheses. Examples are given where this formalism is in qualitative agreement with experiment, as opposed to results of the syntheses or of earlier theoretical tabulations. The theory of detailed corrections is summarized briefly.

There are regions of collective, valence, or band structure indicated in Ref. 16 which are not accounted for in the revised formalism presented here, while there are regions near edges and at higher energies accurate to within a few percent in the current calculations which are not adequately represented by Ref. 16 (or other methods). Where the preferred model is not obvious, the model variation may be used as an uncertainty. In many cases, the preferred model may be established by comparison to experimental data or by understanding the nature of processes occurring in the given energy regime. Typically errors of the current revision reduce to 1% at high energies away from edges, if photoabsorption is dominant. Uncertainty may reach 10–20% within 30% of edges, where scattering becomes significant, or in the 0.03–1 keV range (dependent on Z); and can be larger for energies less than 0.03 keV, regions of (collective) valence resonances, and in the near edge region for particular edges with bonding effects. There are tendencies for all schemes to fail below 0.1 keV (approaching a factor of two or more error).

The tabulation presented here resolves many of the difficulties encountered with previous tabulations, while some aspects remain to be treated in greater depth in the future, perhaps including aspects of collective behavior and near-edge effects. Improvement in application would follow use of better f_{rel} and f_0 values, possibly allowing extension to higher energies and momentum transfers.

14. Acknowledgments

The author is indebted to Sean Brennan, Rupert Perera and John Hubbell for provision of the latest versions of the databases involved and for helpful discussions, without which this could not have been pursued. He is also happy to acknowledge discussions with A. Caticha and support from the Lindemann fellowship and the English Speaking Union of the Commonwealth, and particularly NIST and the Quantum Metrology Division.

16. Explanation of Tables and Tabulated Figures

TABLE 1: Form factors, attenuation and scattering cross-sections, Z = 1–92, from E = 0.001–0.010 keV to E = 400–1000 keV.

Z	Atomic number	f_{NT}	Nuclear Thompson correction to $\text{Re}(f)$ following Eq. (4) and Refs. 13, 14
E	Photon energy in kiloelectron volts (keV).	f_2 , K-shell	Component of f_2 relating to the isolated K-shell orbital
λ	Equivalent wavelength using $E \cdot \lambda = 1.23984244 \text{ keV} \cdot \text{nm}$, from Ref. 51	$\mu = \mu_{PE}$	Photoabsorption cross-section in cm^2/g
Atomic weight	g/mol, used in determination of conversion factors.	μ_K	Component of μ relating to the isolated K-shell orbital
ρ	Nominal density in typical elemental material for users g/cm ³	$\sigma(\text{coh+inc})$	Estimate of coherent and incoherent
μ_s	Conversion for photoabsorption to barns/atom	$= \sigma_{\text{coh}} + \sigma_{\text{inc}}$	scattering cross-section sum
Edge energies	Values taken from Ref. 26	Full lines on plots	Current tabulation (extended) for f_1 , f_2 and μ
Edge labels	Spectroscopic notation ($K=1s$, $L_I=2s$, $L_{II}=2p_{1/2}$, et seq.)	Dot-dash curves	Results reinterpolated from Refs. 15–16, for f_1 , f_2 and μ
f_1 , f_2	Atomic scattering factors in electrons/atom (or eu) for forward scattering using Eqs. (3–18)	Dash in f_2 plots	f_2 K-shell
f_{rel}	Relativistic correction to $\text{Re}(f)$, following Ref. 6 (denoted H82), and Refs. 17–20 scaled as in Refs. 38, 39 (denoted 3/5CL)	Dash in μ plots	$\sigma(\text{coh+inc})$

H Z = 1

Atomic weight = 1.008000E+00 g/mol, nominal density ρ (g/cm³) = 8.9870E–05 μ_s (barns/atom) = $\mu(\text{cm}^2/\text{g}) \times 1.67382E+00$, E(eV) $\mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 4.17463E+07$

1 edge. K Edge energy (keV) = 1.36000E–02

Relativistic correction estimate f_{rel} (H82,3/5CL) = –1.0519E–04, 0.0000E+00 e/atomNuclear Thomson correction f_{NT} = –5.4423E–04 e/atom

E keV	f_1 e/atom	f_2 e/atom	μ cm^2/g	$\sigma(\text{coh+inc})$ cm^2/g	μ_K cm^2/g	λ nm

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z = 1–92 99

Be Z = 4

Atomic weight = 9.012180E+00 g/mol, nominal density ρ (g/cm³) = 1.8450E+00

μ_s (barns/atom) = μ (cm²/g) × 1.49651E+01, E (eV) μ (cm²/g) = f_2 (e/atom) × 4.66927E+06

2 edges. Edge energies (keV):

K	1.11000E-01	L	I	8.42000E-03
---	-------------	---	---	-------------

Relativistic correction estimate f_{rel} (H82,3/5CL) = -1.7882E-03, -6.0000E-04 e/atom
 Nuclear Thomson correction f_{NT} = -9.7394E-04 e/atom

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 129

No Z = 10

Atomic weight = 2.017900E+01 g/mol, nominal density ρ (g/cm³) = 8.3910E-04

$\mu_{\text{e}}(\text{barns/atom}) = \mu(\text{cm}^2/\text{g}) \times 3.35080\text{E+01}$, (eV) $\mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 2.08535\text{E+06}$

4 edges. Edge energies (keV):

K	8.66900E-00	L	I	4.50000E-02	L	II	1.83000E-02	L	III	1.83000E-02
---	-------------	---	---	-------------	---	----	-------------	---	-----	-------------

Relativistic correction estimate f_{rd} (H82,3/5CL) = -1.2490E-02, -6.6000E-03 e/atom

Nuclear Thomson correction f_{NT} = -2.7186E-03 e/atom

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 149

Si Z = 14

 Atomic weight = 2.808550E+01 g/mol, nominal density ρ (g/cm³) = 2.3200E+00

 μ_a (barns/atom) = μ (cm²/g) \times 4.66371E+01, E (eV) μ (cm²/g) = f_2 (e/atom) \times 1.49829E+06

6 edges. Edge energies (keV):

K	1.83890E+00	L	I	1.48700E-00	L	II	9.92000E-02	L	III	9.92000E-02
M	I	1.13572E-02	M	II	5.08305E-03					
Relativistic correction estimate f_{rel} (H82,3/5CL) = -2.6197E-02, -1.5600E-02 e/atom										
Nuclear Thomson correction f_{NT} = -3.8284E-03 e/atom

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z = 1-92 263

As Z = 33

 Atomic weight = 7.492160E+01 g/mol, nominal density ρ (g/cm³) = 5.7200E+00

 $\mu_{\text{abs}}(\text{barns/atom}) = \mu(\text{cm}^2/\text{g}) \times 1.24410\text{E+02}$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 5.61658\text{E+05}$

Edges. Edge energies (keV):

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 287

Rb Z = 37

Atomic weight = 8.546780E+01 g/mol, nominal density ρ (g/cm³) = 1.5290E+00

μ (barns/atom) = $\mu(\text{cm}^2/\text{g}) \times 1.41923\text{E+02}$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 4.92353\text{E+05}$

γ edges. Edge energies (keV):

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 341

Pd Z = 46

Atomic weight = 1.064200E+02 g/mol, nominal density ρ (g/cm³) = 1.2000E+01

μ_{abs} (barns/atom) = $\mu(\text{cm}^2/\text{g}) \times 1.76715\text{E+02}$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 3.95417\text{E+05}$

4 edges. Edge energies (keV):

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z = 1-92 347

Ag Z = 47

Atomic weight = 1.078682E+02 g/mol, nominal density ρ (g/cm³) = 1.0480E+01

μ (barns/atom) = $\mu(\text{cm}^2/\text{g}) \times 1.79119\text{E}+02$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 3.90109\text{E}+05$

Edges. Edge energies (keV):

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 359

In Z = 49

 Atomic weight = 1.148200E+02 g/mol, nominal density ρ (g/cm³) = 7.3000E+00

 $\mu_{\text{A}}(\text{barns/atom}) = \mu(\text{cm}^2/\text{g}) \times 1.90663\text{E+02}, E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 3.66489\text{E+05}$

14 edges. Edge energies (keV):

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 365

Sn Z = 50

Atomic weight = 1.186900E+02 g/mol, nominal density ρ (g/cm³) = 7.3000E+00

$\mu_{\text{abs/atom}} = \mu(\text{cm}^2/\text{g}) \times 1.97090\text{E+02}$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 3.54540\text{E+05}$

4 edges. Edge energies (keV):

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 383

| Z = 53

 Atomic weight = 1.269045E+02 g/mol, nominal density ρ (g/cm³) = 4.9200E+00

 $\mu_s(\text{barns/atom}) = \mu(\text{cm}^2/\text{g}) \times 2.10730\text{E+02}$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 3.31590\text{E+05}$

Edges: Edge energies (keV):

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 401

Ba Z = 56

 Atomic weight = 1.373300E+02 g/mol, nominal density ρ (g/cm³) = 3.5000E+00

 $\mu_{\text{harm/atom}} = \mu(\text{cm}^2/\text{g}) \times 2.28042\text{E+02}$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 3.06417\text{E+05}$

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 413

Ce Z = 58

 Atomic weight = 1.401200E+02 g/mol, nominal density ρ (g/cm³) = 6.6370E+00

 $\mu_{\text{abs}}(\text{atom}) = \mu(\text{cm}^2/\text{g}) \times 2.32675\text{E}+02, E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 3.00316\text{E}+05$

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z = 1–92 437

Sm Z = 62

 atomic weight = 1.503600E+02 g/mol, nominal density ρ (g/cm³) = 7.5100E+00

 $\mu_{\text{atoms/atom}} = \mu(\text{cm}^2/\text{g}) \times 2.49679\text{E}+02$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 2.79864\text{E}+05$

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 461

Dy Z = 66

 Atomic weight = 1.625000E+02 g/mol, nominal density ρ (g/cm³) = 8.5250E+00

 $\mu_i(\text{barns/atom}) = \mu(\text{cm}^2/\text{g}) \times 2.69838E+02, E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 2.58956E+05$

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 479

Tm Z = 69

 Atomic weight = 1.689342E+02 g/mol, nominal density ρ (g/cm³) = 9.2940E+00

 μ_{abs} (barns/atom) = $\mu(\text{cm}^2/\text{g}) \times 2.80522\text{E+02}$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 2.49093\text{E+05}$

19 edges. Edge energies (keV):

THEORETICAL FORM FACTOR, ATTENUATION, AND SCATTERING TABULATION FOR Z=1-92 581

Po Z = 84

Atomic weight = 2.090000E+02 g/mol, nominal density ρ (g/cm³) = 9.3000E+00

$\mu_{\text{a}}(\text{barns/atom}) = \mu(\text{cm}^2/\text{g}) \times 3.47053\text{E+02}$, $E(\text{eV}) \mu(\text{cm}^2/\text{g}) = f_2(\text{e/atom}) \times 2.01341\text{E+05}$

24 edges. Edge energies (keV):
